argument I have seen in favour of chicken-pox being carried in this manner. There is one point which I have never seen emphasised, and which is, I think, not without interest. It is a curious coincidence that the diseases which give trouble in a bed isolation ward are just those diseases which I suppose we all agree practically everybody takes on their first exposure. Would the results as regards scarlet, diphtheria, rubella, and mumps be so good under bed isolation conditions if they were also what one might almost call inevitable diseases? Chapin has suggested that as regards measles the virus may resist hand-washing and so forth more than that of other diseases, but one would have said that a short-lived virus, such as that of measles apparently is, should be easy, not difficult, to disinfect. Dr. Thomson's remarks on whooping-cough are also interesting. I have referred to his 1914 paper and find many of his cases are classed as first-week. If that means the first week of the whoop and not of the cough, one would expect the worst of the infection to be already over. Personally, I consider whooping-cough as only slightly infectious in the first week of the whoop, and to all intents and purposes non-infectious afterwards. It is extraordinary how often cases admitted without whooping-cough into our whooping-cough wards escape the disease; indeed, they hardly ever do take it, though paroxysms go on all round them with no special precautions. Dr. Thomson's observations on the duration of the infectivity of chicken-pox appear to me of great practical value. It is most interesting to find that after three days the risk seems so slight. I may add that a list of cases treated by Dr. Rundle in his ward, which he very kindly sent to me some time ago, made a great impression on me. Whether his system is universally applicable or whether he has not carried it as far as Dr. Thomson, is another question, but he has certainly taught us a great deal about infection which we had not suspected, and it seems to me that it is to his courage and perseverance that we owe the possibility of such a discussion.

Experience at the South-Western Fever Hospital.

Dr. FOORD CAIGER stated that droplet infection was a subject one did not know enough about, but could assume a great deal. He had always classed it as a form of aerial infection. It was only a question of distance between a person near enough to cough in one's eye and a person occupying a bed at the other end of a ward. Dr. Caiger referred to Dr. Thomson's figures, which tended to show the infectivity of chicken-pox was negligible in most cases after the third day of eruption, and said it was the first time he had seen an attempt to indicate the relative infectivity of chicken-pox at different stages in actual figures. He was of opinion that chicken-pox could not be safely treated in cubicles. He had ventured to express that opinion in a paper on cubicle nursing read at the Society of Medical Officers of Health some 10 or 12 years ago, and subsequent experience had but tended to confirm it. He had not had much experience of bed isolation or barrier nursing, as the South-Western Fever Hospital, which he controlled, was provided with cubicles, and so the need for it rarely occurred, but since "barrier nursing" was essentially cubicle nursing without the partitions, he would hesitate to treat chicken-pox under barrier conditions. Referring to Dr. MacIntyre's remarks about the risk attached to the handling of doors in cubicle wards by nursing staff, Dr. Caiger stated that in the cubicle wards at his hospital the doors of the cubicles were swing doors without handles, which were just pushed by the nurse with her knee as she entered or left. Dr. Caiger expressed his belief that measles came next to small-pox and chicken-pox as the disease which it was unsafe to put into cubicles.

Experience at Leeds.

Dr. A. E. A. PEARSON said that after many years' experience of infectious diseases he had come to the conclusion that chicken-pox was a disease that should not be treated in mixed wards. The fact that it did not convey at one time and did at another was

probably due to the time of the outbreak; that when an epidemic was falling, the chances of cross infection were very much less. He was of opinion that chicken-pox was not a contact infection, but conveyed aurally. One would not dream of putting small-pox in invisible barrier wards, and one should not do so with chicken-pox. Measles could be treated by this system better than chicken-pox or whooping cough, but the question arose as to whether any of these diseases should be placed alongside children who had not had them; it was likely to be viewed by outsiders as a stigma on hospitals. The success of any treatment depended largely on ample cubic space, proper ventilation, and well-educated nurses. Dr. Pearson called attention to the striking distance of chicken-pox, and mentioned that he had known it to carry 300 ft. or more in the City Hospital at Leeds; one could only conceive it to have spread by aerial transmission, as the wind will carry small-pox. As regards the human factor, the most elaborate arrangements could be upset by an ignorant or careless nurse.

System Not Justified by Complete Success.

Dr. A. F. CAMERON said that the system called bed isolation seemed to have developed as a result of the acknowledged defects of the segregation ward and the recognition that the ideal system of isolation—that is, the single-bedded room—was much too expensive for common practice. As contrasted with the common segregation ward, to which as far as possible only one disease was admitted, the "bed isolation" ward was in the beginning used for any variety of infection, with the exception perhaps of small-pox. Now we were told that it had been found that measles and chicken-pox were not suitable for this method of hospital isolation. That is to say, that "bed isolation" had with the majority who had tried it failed with the only diseases which had produced administrative trouble in the segregation ward. Was it justifiable to remove a patient from home, where he had not been exposed to a second infection, and knowingly place him in close association with another disease and trust to fallible human nature alone to prevent him becoming infected? Such a system could be justified only by complete success, and, as far as he could judge, in no case had complete success been achieved.

Dr. Thomson's Reply.

Dr. THOMSON, in reply, said that Dr. Goodall's experience strengthened the contention that chicken-pox and measles were much more infectious if introduced into the ward in the incubation stage and were present up to the time of the outcrop of the eruption. He said he had not maintained that a chicken-pox patient was infectious so long as he had vesicles or pustules, nor that he was not capable of causing infection by contact on the eighth day of the disease; but, as the result of his experiments, he had said that probably chicken-pox ceased to be infectious by contact about the end of the first week or the beginning of the second. He thought the free ventilation of a bed isolation ward, which was considered so very essential, suggested a fear of air-borne infection, and that, as suggested by Dr. G. S. Buchanan (now Sir George) in 1912,¹ the windows might be closed altogether for a time in order to see if any difference in the cross infection rate took place. With regard to Dr. Rundle's comments, Dr. Thomson did not wish to dispute the contention that his bed isolation wards were the safest, but what he did complain of was that sufficient information was not given from which to deduce the value of the results. He considered Dr. Rundle's admission that the cases were placed in his bed isolation ward at a somewhat later stage of illness a statement of the utmost importance, and one which greatly explained the difference in the results. Further, diluting the ward with adult patients meant the introduction of a proportion of more or less insusceptible individuals and a consequent diminution of the number of children who were

¹ Proceedings of the Royal Society of Medicine, Epidemiological Section, May, 1912.

susceptible. He said, moreover, that Dr. Rundle erred when he inferred that he (Dr. Thomson) placed a great strain on his staff, for from the first his ward was specially and amply staffed in order that undue strain should be avoided. He thought Dr. Ker's remark about the curious coincidence that the diseases which give trouble in a bed isolation ward are just the diseases which practically all children take might be added to by asking why these particular diseases give such trouble if the infection is by contact only. Dr. MacIntyre thought the fewer the basins and other such articles in a ward the better, but that could scarcely explain the difference between his (Dr. Thomson's) results and those of Dr. Rundle, since he had adopted Dr. Rundle's procedure in such matters. Dr. Thomson, in referring to the danger, mentioned by Dr. MacIntyre, of infection spreading through the nurses opening and shutting doors in cubicle and cell wards, said this could not apply to his wards since the doors were, except in very rare instances, always kept open. In referring to Dr. Pearson's instance of the conveyance of chicken-pox infection for some 300 ft., he said that he thought these instances of the unexpected occurrence of chicken-pox in a ward were generally explained by the incubation of the disease by a patient in the ward, but with a resultant eruption so small as to escape observation. He said he had found this to be so on several occasions after careful examination of all the patients in the ward. He was altogether with Dr. Caiger when he said droplet infection should be classed as aerial infection, and Dr. Thomson suggested that the group should consider the desirability of coming to a definition with a view to avoiding the present confusion of opinion.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

THE EFFECTS OF PHYSICAL EXERCISE ON MENSTRUATION.

A MEETING of this Association was held at the rooms of the Medical Society of London on May 29th, under the presidency of Mr. R. C. ELMSLIE.

Dr. SANDERSON CLOW introduced a discussion on the effects of physical exercise on the function of menstruation in school girls. She said it was universally agreed that physical exercise in some form was necessary for the healthy development of girls as well as that of boys. Recently, diverse opinions had been published on the matter, but those who were of a medical touch with large numbers of girls naturally referred to be guided by their own experience. For several years she had been medical inspector at a large secondary school for girls, where most of the pupils were boarders. During her first year there she was asked by several heads of houses whether it was necessary or desirable for the girls to lie down and rest during their menstrual period; she believed the general rule was that during this time the only form of exercise permitted was walking, the girl being allowed to lie down if she did not feel well, to lie on her bed and read a novel instead of taking the daily walk. The result was that an increasing number of the girls expressed themselves as too unwell to take part during these days in the ordinary school life. It was the custom to attribute the pain they complained of to their having indulged in too strenuous exercise in their games, and accordingly these were prohibited for three days. Dr. Clow was sure this amounted to a large waste of time and a quite unnecessary interference with the school routine, and, more important, that it laid the foundation of much avoidable suffering in a later period of life. She therefore sought opportunities of a talk with each separate girl of the age of puberty, during which she questioned her as to her habits and feelings at these times, telling her that the advice given before the interview was over was not to be followed without the approval of those responsible for her. At these talks the speaker insisted that

menstruation was not a malady, but a natural physiological function: that it was quite natural during the period for the girl to be free from pain or unusual sensations, and she advised a continuance of the daily bathing in warm water right through the period. Finally, she told the girl that if she felt poorly at those times, she should have medical advice, as such advice now might save much trouble and illness later in life.

The girls under Dr. Clow's care at the school and at a training centre for girls ranged from 11 to 25 years of age. The total number of girls she talked to and questioned was 1818. At the first interview, before any advice had been given, 70 per cent. stated they were free from menstrual troubles. At the second interview, after an interval, this figure was raised to 93 per cent. The general impression throughout the profession was that suffering during the menstrual period was the rule, a state of belief for which the British text-books on obstetrics and gynaecology were largely responsible; even the latest editions of well-known works on the subject perpetuated the idea. She read extracts from several, showing that the authors regarded semi-invalidism as the usual accompaniment of the function. The point to bear in mind was that the authors of text-books were not in touch with normal people, but with the abnormal and diseased; hence medical officers to schools, colleges, and factories, had opportunities of acquiring a much better understanding of the state of affairs in the ordinary girl and young woman. If the text-book teaching on the subject could be replaced by the truer and saner view, one of the greatest stumbling-blocks to women in their careers would have been removed. It was easy to convince the girls, harder to persuade the parents, but hardest of all to convert the members of the medical profession. Most girls began to menstruate at the age of 13, but some began at 12, and a few at 11, and for these girls, full of energy and the joy of life, to be compulsorily deprived of games and other forms of activity two or three days per month was a real hardship. If, as happened only rarely, a girl suffered pain during her first few periods, it was usually only a temporary matter, probably due to a delay in the due balancing of the endocrine secretions. When first Dr. Clow went to her work 67 per cent. said they were healthy at this time. After a short time the number declaring themselves well formed 92 per cent. of the whole, an improvement she attributed chiefly to the continuance of the warm bathing, while much was also due to the continuation of a reasonable amount of exercise and activity, excluding swimming for obvious reasons. Trunk movements she especially advocated. Girls themselves found that unless they had a brisk walk at the beginning of their period they were liable to have pain during it. Dr. Clow declared her belief that if the customary restraint on activity of girls during menstruation were withdrawn, one generation would see the end of most of the cases of dysmenorrhœa; certainly most of the cases of dysmenorrhœa which had developed in these girls were cured by the same means. She was fully aware that severe spasmodic forms which had resisted treatment were not likely to yield to what she was now advocating, and to expect it would be absurd. Only 5 per cent. of the sufferers were compelled to lie down because of it, and this figure among the girls under her observation had now been reduced to 1.5 per cent. If in those who said they suffered there were apparent a hypersensitiveness, she prescribed an analgesic, which helped toleration of the required bathing. In some the dysmenorrhœa occurred only on holidays, and this she found to be due to the restriction as to exercise imposed by the mother at home. The report of the Consultative Committee appointed by the Board of Education issued three months ago on differentiations in the curricula for boys and girls stated that it was safer for girls not to have their games and drilling during the period; on the other hand, THE LANCET¹ published an address by Dr. Sarah Gray, of Nottingham, warning against the

¹ THE LANCET, 1922, ii., 1261.

dangers of the periodical rest, remarking that exercise might become the future form of treatment for both menorrhagia and dysmenorrhoea. In America there seemed to be a much more healthy attitude towards the subject, and Dr. Clow read extracts from several declarations on the subject which supported her own contentions. Eighty-four per cent. of the students at the training college under the speaker's inspection were accustomed to make no difference in their habits and games during the period, and 84 per cent. of the students were free from menstrual disability; these figures subsequently rising to 93 per cent. and 95 per cent. respectively. Turning to the industrial side, she said that over 10 per cent. of the girls in an industrial establishment might be expected to report at the hostel during any given month, and three-fifths of the staff of one establishment reported during a year on account of menstrual trouble, excluding those so severely ill that they had to remain at home. Prolonged standing was said to be the chief contributing factor to these troubles. In America it was urged that there should be a systematic and detailed keeping of menstrual notes, but Dr. Clow thought this would encourage too much concentration on the function, and might lead to introspection. She concluded by advocating the issue of leaflets setting out briefly and plainly the main reasons, which she had elaborated, for regarding menstruation as a natural and not a pathological function.

Discussion.

Dr. C. E. SHELLY expressed the hope that Dr. Clow's paper would receive wide publicity, as it was a valuable contribution to the subject. He knew many, including nurses, who continued as usual during the period, even to the taking of their cold bath. But the chief support of Dr. Clow's thesis he knew of was supplied by the case of the fisherwomen of Brittany. The fishing vessels had to beach some distance out, and the women waded, carrying the fish, through the surf, and walked to the market, where they stood in their wet clothes and sold their catch. Yet they had practically no menstrual troubles; these only came on when, through stress of bad weather in the winter, this arduous work ceased.

Dr. MARY BLAIR said she had put into practice the principles Dr. Clow had been advocating, as she regarded them as thoroughly sound. There prevailed extraordinary ignorance on the subject of menstruation. She saw medically many women candidates for Civil Service appointments, and probably 90 per cent. of them did not take baths or exercise during their period. Her advice was that girls should look after their baths, constipation, and exercise; if they had dysmenorrhoea, this treatment cured most of them. She agreed as to the desirability of the issue of a simply-expressed leaflet on the subject.

Dr. SYBIL OVERTON also agreed, and mentioned specially the prevalence of indigestion in school-girls.

The PRESIDENT complimented Dr. Clow on her contribution. The main obstacle to her crusade being successful was that those who were looked up to as the leaders of the profession in these matters were concerned with dealing with the abnormal; therefore it might be a long time before she got her way. Many text-books were out of date by the time they were published. Dr. Clow could not expect to convince the majority of grown women; the great hope was from the education of the young, teaching them that menstruation was a perfectly natural function, and that the less notice they took of it in ordinary life, the better. He believed this view would prevail if only the medical women would continue this teaching and investigation on the lines Dr. Clow and others had adopted.

Dr. CLOW briefly replied. She said she had met with some cases of vomiting during the period, but sometimes she was able to check it by giving a powder and suggesting to the girl that she had nothing wrong with her. She was convinced it was sometimes a psychological upset.

Reviews and Notices of Books.

INTERFACIAL FORCES AND PHENOMENA IN PHYSIOLOGY.

By Sir WILLIAM M. BAYLISS, M.A., D.Sc., F.R.S., LL.D., Professor of General Physiology in University College, London. London: Methuen and Co., Ltd. 1923. Pp. 196. 7s. 6d.

THIS book, based on the Herter Lectures given in 1922, contains an account of the various physiological phenomena, in which an important part is played by the forces which manifest themselves at the boundaries where immiscible substances are in contact with each other. Much of the matter is devoted to the subject of the colloids, in which the great development of surface is responsible for many properties of physiological significance; one of these properties is that of adsorption. As particular instances of colloidal systems, where remarkable phenomena are displayed, the properties of haemoglobin and of enzymes are discussed. The cell-membrane furnishes another instructive example of surface phenomena, the study of which leads up to a chapter on electrical phenomena in cells, and one on the properties of protoplasm from the physico-chemical point of view. A chapter on muscle, nerve and gland cells, and a general survey of the subject completes this thoughtful and readable book. Some of the remarks in the last chapter are well worth quoting; for example: "It is indeed difficult or impossible to find a scientific justification for the separation of biochemistry from biophysics." "No physiological laboratory can avoid the necessity of its own chemical department." "It was always insisted on by Claude Bernard that physiology is an independent science, to be cultivated for its own sake and irrespective of ultimate practical applications." Sir William Bayliss holds that the movement in some quarters to confine the physiology taught to the medical student to that part of the science which is at the moment seen to be of immediate direct application to clinical practice is to be regretted. In view of the overcrowding of the curriculum there is something to be said for this movement, but the difficulty remains that we can hardly foresee what branches of physiology are likely to be essential to medicine ten or even five years hence, when the student goes forth to practise. Many qualified men are even now regretting the small amount of time allotted to practical biochemical investigations in their student days.

ORTHOPÆDIC SURGERY.

By Sir ROBERT JONES, K.B.E., C.B., F.R.C.S., &c., Lecturer on Orthopædic Surgery, Liverpool University; and ROBERT W. LOVETT, M.D., F.A.C.S., Professor of Orthopædic Surgery in Harvard University. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. With 712 engravings. Pp. 699 + xv. 42s.

IT is some time since any authoritative work on civil orthopædics has appeared in English, and the recent appearance of the "Orthopædic Surgery" of Sir Robert Jones and Prof. Lovett is welcome both on account of the eminence of its authors and of the need of an up-to-date book on this special branch of surgery. It may be taken to supersede the work by Bradford and Lovett on the same subject, while it has the additional advantage of presenting to us the wealth of experience and the ripe judgment of the late Director of Military Orthopædics in this country. The Boston school of orthopædic surgery occupies a pre-eminent position in the United States, and no better representative of that school could be found than Prof. Lovett. The authors have overcome the difficulties of collaboration at such a distance from one another with success. A major part of the work is taken up by the subject of diseases of bones and joints, and a large proportion of this section is devoted to the

ever-present problem of the treatment of surgical tuberculosis. In writing of these diseases the authors wisely reject the method by which each kind of affection is described as a separate entity, and prefer to describe joints in general and particular with reference to their reactions to disease, afterwards discussing the phenomena presented by the various parts when they react to each morbid stimulus. Traumatic affections of joints in general are first dealt with, then come descriptions of the effects of injury on each of the individual joints. For that troublesome affection known as "slipping patella" the authors recommend Goldthwait's operation as the most generally satisfactory, but other procedures are described. The well-known methods of Sir Robert Jones for treatment of internal derangements of the knee-joint are fully set forth, as also is the treatment of recurrent dislocation of the shoulder.

It is probable that no class of case offers such a fruitful field for the proceedings of the bone-setter as does that classified under "stiff-joint." Especially is this true of the looser adhesions which persist after treatment of more serious conditions, and which are often the cause of much disability and pain to the patient. As to when, how, and where to break down these adhesions and thereby restore free and painless movement, there can be no better guide than that provided in Chapter V. Tuberculosis of bones and joints is dealt with on up-to-date principles in five important chapters. It must be a legitimate source of pride to orthopaedic surgeons that the principles enunciated by them during the years when general surgeons were freely exercising and amputating tuberculous joints, are now everywhere triumphant, especially when combined with open air and sunshine. These chapters will be found to contain most of what is to be known of the therapeutics of these forms of disease. The chapter on arthritis deformans recalls to our minds the fact that although surgery cannot cure, it is capable of much improving the functional ability in these patients, by substituting a stiff and painless joint for a painful and partially movable one. In this disease arthrodesis offers far greater prospects of benefit than arthroplasty as at present practised. Diseases of bones and joints caused by organisms other than *B. tuberculosis* are not so generally regarded as coming under the care of the orthopaedic surgeon, but since their treatment is governed by the same principles their inclusion here is fully justified. Haemophilia, intermittent synovitis, Charcot's disease, gout, muscle and bone atrophy, and functional contractions and deformities occupy a short but useful chapter. Of gout we are told that it is more common in Great Britain than in America. If that is the case it must be a very rare disease across the Atlantic, for manifestations of true arthritic gout are now rare in England and seem to be becoming more rare year by year. Even the "suppressed gout," dear to the puzzled practitioner and to the well-to-do sufferer, who is lattered by the attribution to him of no vulgar disorder, seldom figures nowadays in a diagnosis. Those obscure back troubles which cause so much suffering to the patient and tax the resources of surgery and medicine, are well discussed in the chapter on the affections other than tuberculous of the bones and joints of the spine and thorax. Their prevention and their cure occupy more of the time and thoughts of surgeons in the United States than of those in this country, but here, too, the subject is important enough for us to recommend this chapter also to British readers. In the chapter on affections of adult bone we welcome an expression of opinion by Sir Robert Jones that in Paget's disease severe deformities of the long bones should be corrected by operation, especially since by relieving tension such proceedings generally also relieve pain.

Spastic paralysis and anterior poliomyelitis—especially the latter—are to the orthopaedic surgeon the most important of the diseases of the nervous system. In the treatment of the latter disease recent epidemics in the United States have lent great authority to the already wide experience of Prof. Lovett, and

sound advice on this subject is to be found in Chapter XXI. The chapter on muscle training, which is of paramount importance in the re-education of these cases, should also receive special study. The treatment of congenital deformities has become more or less stereotyped, but the chapter on congenital dislocation of the hip should not be passed over without notice. The bloodless method may now be considered to hold the field. We must regretfully admit that if there is nothing strikingly new in the chapter on lateral curvature of the spine, it is because the therapeutics of this opprobrium chirurgiae are less successful than their prophylaxis.

The authors disclaim any encyclopædic character for their work, and it is clear that such a book on orthopaedic surgery would have needed at least two such volumes as this. The methods here set forth are those that have found favour in the practice of the authors, and for a full account of other methods it will still be necessary for the earnest student to read other manuals and monographs. There are, too, some lacunæ, such as the lack of reference to Dupuytren's contraction of the palmar fascia. But readers may rest assured that in this book they will find a notable and authoritative contribution to orthopaedic literature. The book is printed in clear type and is well and freely illustrated. A fuller index would have been a valuable addition.

ANIMAL PARASITES AND HUMAN DISEASE.

Second edition. Revised by ASA C. CHANDLER, M.S., Ph.D., Instructor in Biology, Rice Institute, Houston, Texas. London: Chapman and Hall, Ltd.; New York: John Wiley and Sons, Inc. 1922. Pp. 572. 22s.

HUMAN parasitology, at any rate as far as the tropical parasites are concerned, has undergone in recent years kaleidoscopic changes, and the author has attempted to trace in simple and intelligible language the course of these researches. Although a great deal of information has been culled from current literature, the result cannot be said to be satisfactory, either to the lay reader or to the student. The former will not grasp the import of the many technical terms introduced, while the latter will find the mass of details and scientific data to be presented in an uncritical spirit. The illustrations are poor and are adapted from other well-known works on parasitology.

The subject-matter embraces the greater part of tropical medicine, as the list of references, standard works, and periodicals which are given as sources of information will show; from these the work has apparently been compiled, and there is little evidence of originality.

WEIL'S DISEASE.

Über die Pathologische Anatomie der Spirochaetosis Ictero-hæmorrhagica Inada (Weilsche Krankheit). By Dr. RENJIRO KANEKO, Professor in the Imperial Kyushu University of Fukuoka. Vienna: Rekola Verlag. With six coloured and two uncoloured plates. 1922. Pp. 181.

THIS work is an exhaustive monograph embodying the results of the author's researches upon the pathology of Weil's disease, a common malady in Japan. In the preface the author gives his reasons for the steps he has taken to have this work produced, and it would appear that, owing to the publication of his earlier researches on this subject in Japanese, his work, the importance of which cannot be denied, has not received the recognition in Western literature that it deserves. The pathological changes of Weil's disease as they affect every organ of the body are described with the most minute detail, especial attention being given to the liver, where focal necrosis, with its attendant changes, can be studied, but somewhat similar changes are present in the cardiac and somatic muscles. The quite characteristic kidney changes are also minutely described, and, in fact, the whole report is

so detailed and laborious that it cannot be adequately digested save by the advanced student of this subject. It therefore fits in as a necessary complement to the monograph of Martin and Pettit where the symptomatology and ætiology of infectious jaundice are described at length.

Fine plates adorn the monograph.

THE MIDWIFE: HER BOOK.

Edited by ALICE GREGORY, Hon. Secretary of the British Hospital for Mothers and Babies, Woolwich. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 268. 7s. 6d.

THIS little book is written by three of the original staff of the British Hospital for Mothers and Babies and by some of their pupils. It contains a number of chapters dealing with various matters concerned with the training and practice of midwives and maternity nurses which give a great deal of most valuable and useful information. The rest of the book is made up of a number of sketches of patients, their friends, and their surroundings, written with a mixture of humour and pathos which must appeal strongly to those who have worked in similar conditions and are familiar with the scenes depicted. A charming little book which should do much to help those who, as the editor says in her preface, are putting up a good fight in circumstances often depressing and difficult.

THE DAYS OF A MAN.

By DAVID STARR JORDAN. In two volumes: Vol. I., 1851-1899; Vol. II., 1900-1921. London: George G. Harrap and Co., Ltd. 1922. Pp. 710-906. £3 3s.

THERE is a story of an enthusiastic lady who, on visiting Venice for the first time, wrote to a friend, "I am really in Venice, sitting at my window overlooking the Grand Canal, and drinking it all in. At times life seems almost too full." Dr. Jordan must, we think, have felt the same many times during his long and busy life, the incidents of which are noted in two large volumes. He seems to have been everywhere and done everything; he has taught and farmed, bred merino sheep, and studied fishes. He has been president of two American Universities, that of Indiana and of Leland Stanford Junior University. He has served on Fishery Commissions in the Pacific, Alaska, and Japan, as well as on a Sealing Commission. He has travelled nearly all over the world and the chief of his multifarious industries has been the most laudable one of working for peace. He has met people in every rank of society and has an eminently catholic mind. He reminds us in many ways of Disraeli's "Mr. Vavasour," who "saw something good in everybody and everything, which is certainly amiable and perhaps just, but disqualifies a man in some degree for the business of life, which requires for its conduct a certain degree of prejudice." Anyway, he has produced a remarkably interesting book, in which, among other things, we find that he traces his ancestry back to Charlemagne. Dr. Jordan possesses a medical degree, not honorary, but given after what would be now called a most inefficient training, a fact which he himself notes. It is interesting to see that he says that the Indiana Medical College was originally a branch of the State University, but in the 'sixties the connexion became purely nominal, as the State legislature voted to discontinue both its medical and law schools, asserting it to be "no duty of the people to help men into these easy professions." It is not our business to say whether the law is an easy profession, but Heaven help the man who goes into the medical profession thinking that easy.

We cordially recommend Dr. Jordan's book, for the reader will find something worth reading on every page.

JOURNALS.

JOURNAL OF LARYNGOLOGY AND OTOTOLOGY. March and April, 1923.—In the March number Mr. D. E. S. Wishart, of Toronto, gives an interesting and instructive account of the neuro-otological examination of 11 verified cases of brain-tumour. The cases have been divided into three groups: (a) Subtentorial—intra-cerebellar, (b) subtentorial—extra-cerebellar, and (c) supra-tentorial tumours. The clinical examinations and the final verification by operation or autopsy are very fully recorded. The intra-cerebellar tumours did not affect the hearing, but did interfere with the vestibular function; this interference tended to be bilaterally symmetrical, and the reflexes from the vertical canals were affected before those from the horizontal canals. Extra-cerebellar tumours—that is, growths in the cerebello-pontine angle—affected both cochlear and vestibular functions of the same side. The two cases of supra-tentorial tumours occurred in the frontal lobes and did not interfere with either function. The caloric tests of the vestibular function were used more than the rotation tests.—Dr. Albert A. Gray records observations on four cases of otosclerosis who hear better in circumstances in which one would expect the hearing to be worse, and he labels this condition "otosclerosis paradoxus." One case heard better whenever she had a cold in the head, another when suffering from her annual attack of hay-fever; the third, feeling faint in an overheated room, went to an open window, when she heard quite clearly for about two minutes; while the fourth, feeling faint after a long motor ride, took some brandy with a similar effect.—Mr. T. B. Layton contributes a suggestive discussion on malnourishing and allied conditions of deafness, ranging from pure functional deafness to a conscious and deliberate attempt to deceive.—The April number begins with a speech by Sir Sydney Russell-Wells on the aim and use of special hospitals, delivered at the annual dinner of the Central London Ear and Throat Hospital. In his opinion the special departments of the general hospitals are the best for undergraduate teaching, but the special hospitals are ideal for post-graduates. Special hospitals could and should coöperate to form what would quickly become the London Post-Graduate School.—Drs. A. Logan Turner and Thomas Sprunt describe a case in which a finger-like process projected down from the lower pole of the left tonsil and contained islands of cartilage; they consider that the histology of this case supports the theory that such cartilaginous nodules are of embryonal origin.—Mr. J. D. Lithgow discusses the mechanism of oculo-vestibular coördination as a factor in the survival of the species, in view of the value of such mechanism in attack and escape.—Mr. B. Seymour Jones reports the case of a small sessile growth on the left vocal cord of a man aged 64, removed by thyrotomy with Lambert Lack's technique, and reported by Mr. Wyatt Wingrave to be a "mesothelioma growing in cylindrical masses, undoubtedly malignant," to be classed as a "perithelioma of mesothelial genus." There has been no recurrence after three years.—Mr. Nicol Rankin reports three cases of zygomatic mastoiditis, two of which showed extensive disease of bone with exposure of the dura mater.

BRITISH JOURNAL OF OPHTHALMOLOGY. March, April, and May, 1923.—In the March issue F. M. B. Walshe discusses a Case of Secondary Carcinomatous Infiltration of the Pia-Arachnoid of the Brain, presenting exclusively Ocular Symptoms during Life: Meningitis Carcinomatosa. Commonly, this form of carcinomatous involvement of the central nervous system produces a clinical picture akin to that of an acute meningitis. This case began with diplopia and headache—the former due to paralysis of the left external rectus, followed by optic atrophy of the left eye without manifest loss of visual field and no other localising symptoms. Post mortem naked-eye examination revealed little abnormal, except that

the left abducens nerve was slightly thickened and opaque in appearance. Microscopic examination revealed that the pia-arachnoid in the regions of the thickening, and also in places where no thickening was visible to the naked eye, was the seat of a malignant infiltration by a cubical-celled carcinoma. There was an intense invasion of the trunk of the sixth nerve and a less intense invasion of the optic nerve. The isolated occurrence of ocular symptoms from such a cause, says the author, must be extremely rare, but he gives references to some more or less similar cases in German literature. It was supposed that the growth was secondary to a primary focus in the alimentary tract, although there was no proof of this. On the pathological side the extreme fineness of the meningeal involvement, and the fact that at autopsy it was entirely missed, indicate the importance of a routine examination of the meninges in all cases in which visceral carcinoma has been complicated by the development of definite symptoms referable to the nervous system in its clinical course.—R. E. Wright discusses the Importance of Radiography in Doubtful Cases of Optic Atrophy with Special Reference to Pituitary Disease. Out of 40,000 eye-patients seen in Madras there were eight in which trouble in the neighbourhood of the sella was suspected. In three of these the optic atrophy so overshadowed all the other symptoms that without radiographs the cases might easily have remained undiagnosed. The paper is chiefly of interest on account of the radiographic prints and notes by Captain T. W. Barnard.—There is also a paper by Dr. H. Hartridge expounding Mrs. Ladd Franklin's theory of colour-vision.—In the April issue Alan W. Sichel writes on So-called Glassworkers' Cataract Occurring in Other Occupations, with report of two cases. Following Criddland, the writer proposes to call this form of cataract which occurs in workers subjected to great heat "ray cataract."—George Young communicates a paper on Macular Perception in Advanced Cataract. The author has devised a method of testing whether the macular function is or is not intact, which he has found useful in deciding whether or not to operate in cases of cataract.—Leslie Buchanan, in a paper entitled Monocular Optic Neuritis, relates four cases in which the monocular optic neuritis was due to exposure to cold. In each case recovery was complete.—The number also contains articles by J. Lockhart Gibson on Siderosis, and by A. Ticho, of Jerusalem, on Ophthalmomyiasis, the name used to describe the several symptoms caused in the eye and its annexes by the larvæ of diptera.—In the May issue, among other papers, there is one by I. Neame on Two Cases of Tumour of the Optic Nerve, and one by F. A. Williamson Noble on Endothelioma of the Orbit, both of them well illustrated.—R. R. James recalls a paper by Sir D'Arcy Power in THE LANCET (1895, i., 1357) dealing with the Ophthalmic History of Samuel Pepys, and offers an alternative explanation for Pepys's eye troubles.

THE TROPICAL DISEASES BULLETIN, May, 1923, contains a review of recent literature on blackwater fever, by Warrington Yorke. The review includes notice of papers of considerable interest in view of the reputed discovery of spirochætes in the blood in this disease by M. Blanchard and G. Lefrou: the organisms are demonstrated by a method of triple centrifugation and have been named *Spirochæta biliohæmoglobinuriae*, but are possibly identical with *Leptospira icterohæmorrhagiae*. Plague, cholera, and enteric fevers are reviewed by J. H. Tull Walsh; undulant fever, pappataci, and Rocky Mountain spotted fever, by P. W. Bassett-Smith; beriberi and scurvy are also dealt with by the same authority. There are notes on amœbiasis, dysentery, and sprue by P. Manson-Bahr. The section on Medical Zoology is by A. Alcock, and a Miscellany is compiled by A. G. Bagshawe.

THE GENERAL MEDICAL COUNCIL.

THIRTEEN penal cases came before the Council during the session. The cases were heard in public; the Council deliberated upon them in camera, and the decisions were publicly announced as usual. The cases were briefly as follows:—

TUESDAY, MAY 29TH.

The Case of James Law.—This practitioner, judgment upon whose case was postponed from December, 1922, till November, 1923, was reported to have died in March.

The Case of Robert Bell.—This practitioner, registered as of 15, Half Moon-street, Mayfair, London, W. 1, appeared before the Council in May, 1922, on a charge of treating a patient for "inoperable" cancer without seeing or examining the said patient, the attention of the Council having been drawn to the case by a committee of Warrington practitioners. The facts alleged were proved to the satisfaction of the Council in 1922; but in view of the circumstances of the case, and in the light of evidence as to Dr. Bell's unexceptionable conduct in the interval the Council, after the usual deliberation in camera, did not see fit to direct erasure of his name from the Medical Register.

The Case of William Joseph Ryan.—W. J. Ryan, registered as of 126, King's Cross-road, London, W.C. 1, had been convicted of drunkenness and fined on three occasions between 1918 and 1921. The Council, in the light of Mr. Ryan's promise to abstain from drink in the future, did not see fit to direct erasure of his name from the Medical Register.

The Case of David Charles Williams.—D. C. Williams, registered as of Brynffedwen, Treherbert, Glam., was found to have been guilty of a breach of the Council's notice with regard to the practice of "covering," having permitted an unregistered person (his "dispensary attendant") to practise in his presence as if he were registered in the Dentists Register. Mr. Williams had supported his assistant's claim to be so registered by a certificate in which he stated that the said assistant had performed "all operations usually entrusted to dentists." The Dental Board, however, had found that the assistant could claim only the status of a mechanic, and had not admitted his name to the Register. The terms of Mr. Williams's certificate, therefore, laid him open to a charge of covering. After deliberation the Council, believing that Mr. Williams had not realised the gravity of his position in the matter, postponed judgment for six months, with the usual proviso as to conduct meanwhile.

The Case of John Francis Smyth.—J. F. Smyth, registered as of Oakdale, Blackwood, Mon., was summoned on a charge of bigamy and falsification of a marriage register, for which he was sentenced in November, 1922, at Swansea Assizes, to six months' imprisonment. The Council found that although the facts alleged were proved, the presumption of the death of the wife had been reasonable, in consideration of which they did not see fit to direct erasure of Mr. Smyth's name from the Medical Register.

WEDNESDAY, MAY 30TH.

The Council continued their consideration of penal cases.

The Cases of Frederick Henry Browne and Benjamin Damer Merrin.—These two cases were considered together, the practitioners in question (registered as of Hillside, Upholland, Wigan, and of Cambridge House, Cambridge-road, Rathmines, Dublin, respectively) having signed certificates for National Health Insurance purposes, and given prescriptions, all relating to the same patient, without having first seen or examined the said patient. The certificates and prescriptions had formed the subject of an inquiry by a Medical Service Subcommittee under the National Health Insurance Acts, and the cases were reported to the Council by the Ministry of Health. The finding of the Council was that the

certificates had been given in a lax and careless manner, and that such laxity was worthy of severe censure. Having regard to the previous good characters of the practitioners and to the warning received by them during the course of the proceedings, the Council did not see fit to direct erasure of their names from the Register.

The Case of Nicholas Cullinan.—N. Cullinan, registered as of Dempsterville, Felling-on-Tyne, had been summoned to appear on a similar charge—i.e., of signing certificates for National Health Insurance purposes without having seen or examined the patient to whom they related, with the additional charge of permitting his (Dr. Cullinan's) wife to issue a certificate in his name. The case was reported to the Council by the Ministry of Health. The Council warned this practitioner concerning the gravity of laxity and carelessness in the issuing of certificates, and did not see fit to direct erasure of his name from the Register.

The Case of James Samuel Risien Russell.—This practitioner, registered as of 44, Wimpole-street, London, W. 1, was summoned to appear before the Council on a charge of having issued in January, 1923, to a former patient, in connexion with a claim to a disablement allowance under the War Risks Compensation Scheme, a certificate stating (inter alia) that he was at the date of the certificate under his (Dr. Russell's) care and treatment, and was justified in applying for a pension, as his present disabilities made him quite unfit to ever resume his duties; whereas he (Dr. Russell) had not seen or examined the said patient since 1918. This case was reported to the Council by the Marine Department of the Board of Trade.

The main facts of the case, made plain during the course of the proceedings, were that Dr. Russell had recently parted with a very experienced secretary when the certificate was given; that he had frequently entrusted the drafting of certificates to the said secretary, and that his new secretary, who had previously acted in a junior capacity, was at the time greatly overburdened with work. He had been requested by a former patient, Mr. N. S. Wicks, to supply him with another certificate to replace one given in 1918, which Mr. Wicks had lost. Dr. Russell instructed his secretary to look up the certificate issued in 1918 and draw up another on the same lines, "bringing it up to date." When the certificate was brought to him to sign Dr. Russell had not his glasses with him; he asked the secretary to tell him its contents, and she, instead of reading it through, merely gave him the gist of what she had written before he signed it.

Two letters referring to the certificate were addressed to Dr. Russell by the Board of Trade, but owing to pressure of work upon the secretary these were not answered, or apparently seen by Dr. Russell at all, until the Board of Trade had put the matter in the hands of the General Medical Council.

THURSDAY, MAY 31ST.

The Case of James Samuel Risien Russell (continued).—The Council immediately proceeded to consider this case in camera. The decision was later announced, the Council finding that the facts alleged against Dr. Russell had been proved upon his own admissions. His statements had been seriously weighed by the Council, in their bearing on the degree of culpability attaching to the facts proved, and it was decided that although they might serve to explain how the misleading certificate came to be framed and attested, they did not remove the discredit of reprehensible carelessness in the discharge of a serious professional duty. Such carelessness might readily amount to disgraceful conduct and merit the stern judgment of the Council. It certainly called for grave professional censure. The Council believed, however, that Dr. Russell had very imperfectly realised his professional responsibilities, and also that the proceedings might warn him effectively of the danger attaching to such methods, and were prepared to assume that he did not of set purpose intend his certificate to mislead or deceive. The

Council, therefore, did not direct the Registrar to erase Dr. Russell's name from the Register.

The Case of James Robert Stott.—J. R. Stott, registered as of 4, Brunswick-terrace, Craigie, Perth, was summoned to appear on a charge of having by countenance or assistance knowingly enabled a woman not certified under the Midwives Act, 1912, to attend women in childbirth, and of having in some cases signed maternity benefit certificates, enabling the woman in question to practise as if she were certified under that Act. The complainants in this case were the Surrey County Council, who were represented by Dr. H. Joseph Cates, their medical officer of health. Dr. Stott attended, accompanied by Mr. Oswald Hempton, solicitor, instructed by the Medical Defence Union. It was argued during the course of the proceedings that Dr. Stott was not aware, until an inquest was held on a child whose mother he had attended after the birth, that the woman in question (who had been present at the birth) was not a certified midwife. He thereupon informed her that he could not attend in cases where she had been called in to a confinement. There was no evidence that any case attended by this woman was not properly cared for by her.

The Council found the facts alleged against Dr. Stott to have been proved, and postponed judgment until their May session, 1924, making the usual requirement as to evidence of behaviour in the interval.

FRIDAY, JUNE 1ST.

The Case of Walter Ernest Tate.—The case of W. E. Tate, registered ("Dentist, 1921") as of Dulais House, Alfred-street, Neath, was considered by the Dental Board of the United Kingdom on May 9th. Mr. Tate had been convicted in February at Guisborough Petty Sessions of embezzlement, and the Dental Board found that his name ought to be erased from the Dentists Register. The Council directed that it be erased.

The Case of James Daniel Williams.—The case of J. D. Williams, registered ("Dentist, 1921") as of 152, Ladybrook-road, Sparkbrook, Birmingham, was considered by the Dental Board of the United Kingdom on May 9th. Mr. Williams had been convicted at Exeter Assizes in November, 1906, of using an instrument to procure abortion, and sentenced to five years' penal servitude. He was at that time a chemist. In a statutory declaration made by him on April 24th, 1922, when applying for registration under the Dentists Act, 1921, he stated that he had "never been convicted in H.M. Dominions or elsewhere of an offence which, if committed in England, would be a felony or misdemeanour." The Dental Board found that Mr. Williams's name ought to be erased from the Dentists Register. The Council directed that it be erased.

The Case of Ernest Mayer.—E. Mayer, of Swiss nationality, registered as of Tynewold Villa, Treherbert, Glam., was summoned on a charge of (1) permitting posters printed at his expense to be exhibited at a colliery and in houses, inviting workmen desirous of choosing himself as their panel doctor to do so, and giving directions as to the means of effecting the transfer; and (2) giving implied, if not expressed, consent to house-to-house canvassing carried out with the same intention. The case was reported by the Welsh Board of Health. The Council found that the first charge was proved, and the second not proved. The decision of the Council was postponed till the November session, with the usual proviso as to character and conduct in the interval.

The Case of Edward Newton.—E. Newton, registered as of 60, St. Chad's-road, Tilbury, Essex, was summoned on a charge of (1) causing or permitting to be exhibited in a workmen's club at Tilbury a notice headed "National Insurance," and stating that he attended there on certain days, and that anyone wishing to transfer to his panel could do so without medical cards; (2) causing or permitting verbal announcements to be made in that club, and in

another club in Tilbury, relating to transfer to his panel; (3) distributing National Health Insurance cards to persons who were not patients of his or on his panel list.

Dr. Newton attended, accompanied by Mr. Alexander Neilson, K.C., with him Sir Robert Aske, his counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors to the London and Counties Medical Protection Society. The complainants were the Medical Defence Union, represented by Mr. Oswald Hempson, solicitor. In the course of proceedings it appeared that the secretary of the club was fully responsible for the drawing up and displaying of the notice "for the benefit" of members of the club, and that two members who were proved to have transferred to Dr. Newton's panel after the notice was displayed had done so entirely on their own initiative, without having seen the notice.

SATURDAY, JUNE 2ND.

The Case of Edward Newton (continued).—The hearing of this case was concluded. The Council found that none of the charges against Dr. Newton had been proved.

This concluded the hearing of penal cases.

REPORTS OF COMMITTEES AND OTHER BUSINESS.

Province of Quebec.

On Friday, June 1st, the Executive Committee reported that at their meeting on May 28th they considered an application from the College of Physicians and Surgeons of the Province of Quebec for the recognition of their licence, granted, after examination by a Board appointed by the College, to graduates in medicine of Universities outside the Province. The Committee directed as follows: "That the Registrar be directed to register in the Colonial List of the Medical Register any person who holds the licence or membership of the College of Physicians and Surgeons of the Province of Quebec, granted after examination in medicine, surgery, and midwifery by the Board appointed for the purpose by the College, together with the licence to practise in the Province of Quebec, provided he satisfies the Registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886."

The report was received and entered in the minutes.

Warning Notices.

The following report by the Executive Committee was adopted:—

At the meeting of the Council on Dec. 1st, 1922, the Executive Committee, in consultation with the legal advisers, were directed to consider and report upon the expediency of amending the Council's Warning Notice No. 5, with respect to advertising and canvassing so as to make its scope more clear and comprehensive. (Minutes, 1922, p. 91.) After careful consideration, in conjunction with the legal advisers, the Committee recommend that the preamble of the notices be the same as before, subject to one or two typographical alterations, the citation of the Dentists Act and reference to dentists being omitted; that a new paragraph, No. 4, relating to dangerous drugs, be inserted; that No. 4 become No. 5; that No. 5 as amended become No. 6; that No. 6 become No. 7; and that a new paragraph be added at the foot.

The new paragraph No. 4, Dangerous Drugs, is as follows:—

"The contravention by a registered medical practitioner of the provisions of the Dangerous Drugs Acts and the Regulations made thereunder may be the subject of criminal proceedings, and any conviction resulting therefrom may be dealt with as such by the Council under the powers given them by Section 29 of the Medical Act, 1858. But any contravention of the Acts or the Regulations, involving an abuse of the privileges conferred thereunder upon registered medical practitioners, whether such contravention has been the subject of criminal proceedings or not, will, if proved to the satisfaction of the Council, render a registered medical practitioner liable to have his name erased from the Register."

The new paragraph No. 6, Advertising and Canvassing (old No. 5 amended), is as follows:—

"The practices, by a registered medical practitioner—(a) of advertising, whether directly or indirectly, for the purpose of obtaining patients or promoting his own professional advantage; or, for any such purpose, of procuring or sanctioning or acquiescing in the publication of notices commending or directing attention to the practitioner's professional skill, knowledge, services, or qualifications, or depreciating those of others; or of being associated with or employed by those who procure or sanction such advertising or publication, and (b) of canvassing or employing any agent or canvasser for the purpose of obtaining patients; or of sanctioning, or of being associated with or employed by those who sanction, such employment;—are in the opinion of the Council contrary to the public interest and discreditable to the profession of medicine, and any registered practitioner who resorts to any such practice renders himself liable on proof of the facts to have his name erased from the Medical Register."

The following is the new paragraph to be added at the foot:—

"The attention of all registered medical practitioners is called to the warning notice which is issued by the Dental Board of the United Kingdom to all registered dentists, and which can be obtained on application to the Registrar of the Dental Board, 44, Hallam-street, London, W. 1."

In the short discussion on the above report, Dr. Bolam said that it was abundantly evident that paragraph No. 6 was on the lines desired by the profession. There was a wide feeling in the profession that the General Medical Council should be in a strong position to take action in cases of "prepared" publicity. This regulation would undoubtedly conduce to a better state of affairs than had hitherto existed.

Mr. Turner spoke of the extraordinarily good effect of the Council's debate on this subject during the November session, 1922. As far as London was concerned, there had been an enormous decrease of practices to which objection might be taken.

Sir Jenner Verrall expressed his satisfaction that the notice provided for the taking up of cases of small infringement of the Council's regulations.

The President pointed out that the action of the Council was not limited by the text of the warning notice.

Regulations Affecting Practitioners.

Mr. Turner moved—

"That the Lord President of the Council be requested to represent to the Government Departments concerned that it is desirable, in the public interest, that any proposed changes in the Dangerous Drugs Regulations, or similar Regulations affecting the legal obligations of medical practitioners, should be communicated to the General Medical Council before they are finally adopted."

Dr. Macdonald seconded the motion. The President made a statement as to the relations of the Committees of the Council and the President with Government Departments when asked to comment on any matters of public interest which came within the purview of the Medical Council. The Council, he said, had no right to receive drafts or copies from Government Departments. Only lately had the courtesy been extended to the Council; and any claim of right would be resented. After some discussion, Mr. Turner withdrew the motion.

Pharmacopœia Committee.

This report, on the motion of Sir Nestor Tirard, was received and approved. The number of copies of the British Pharmacopœia, 1914, sold by the publishers between Nov. 25th, 1922, and May 28th, 1923, was 946 copies. The number sold in the year ending May 28th, 1923, was 2083 copies. The total number sold since the date of publication is 44,437. The Committee had carefully considered a communication from the Privy Council, transmitting a suggestion from the Pharmaceutical Society that the pharmacopœial formula for liquor strychninæ hydrochloridi should be altered, so as to include therein 0.004 per cent. of brilliant green. The Committee, in formulating their

grounds of opposition to the proposal, stated that the question of distinguishing certain poisons by means of artificial coloration is a general one, which merits consideration in connexion with the revision of the Pharmacopœia, but should not be summarily determined, as is proposed, in the case of a single preparation of a single poison. For this and other reasons the Committee were not prepared to advise the General Council to direct this compulsory coloration.

Education Committee.

This report was received and entered in the minutes on the motion of Dr. Mackay (chairman of the Committee), who referred to the advantage which had accrued from the combination of the Registration and Education Committees, carried out at the Council's November session, 1922. Among the items of the report was one relating to new regulations. The Committee had considered correspondence from the British Dental Association asking that dental students be allowed to count *pro tanto* the passes they produced in certain subjects at an examination of an inferior standard passed prior to Dec. 31st, 1922, and to pass in the remaining subjects at the higher standard this year; and that such students be permitted to pass in the remaining subjects at the standard in force prior to Dec. 31st, 1922. The Committee resolved: (1) That medical and dental students be allowed to count *pro tanto* any subjects passed at the inferior standard above referred to; and (2) that all such students must complete their examination in general knowledge by passing in the deficient subjects at the standard at present in force.

Satisfactory evidence as to visitation having been obtained, Worksop College had been added to the list of institutions recognised by a licensing body and approved by the Council.

The recommendations in the report were adopted by the Council.

Examination Committee.

This report was received and its recommendations adopted on the motion of Sir Norman Walker (chairman of the Committee).

Among the items of the report was one relating to the inspection of examinations. By direction of the President, the Chairman "visited" the final examination in midwifery of the University of Cambridge in December, 1922. The substance of his report was to the effect that, with the exception of No. 19 old series (clinical examination), all the recommendations of the Council had been accepted, and were actually in force on the occasion of his visit. Further, while the University authorities still held that it was not practicable to hold a clinical examination in midwifery and gynaecology in Cambridge, they would in future require every candidate to produce a certificate from his teacher stating that he had regularly and diligently attended a practical course on these subjects, and had acquired a competent knowledge of them. As these changes bring the final examination in midwifery in the University of Cambridge into line with nine other licensing bodies, the Committee think it unnecessary to take any further action in the meantime.

As regards returns from the Services, information was received from the War Office that an entrance examination for commissions in the Royal Army Medical Corps had been held. The War Office was thereupon asked if it would furnish a return in regard to candidates similar to that supplied prior to the war. This has been done; but as there were only four candidates for 15 vacancies, all of whom were successful, the result is merely summarised. The Royal Navy and the Indian Medical Service have not resumed the pre-war system of direct entry by competitive examination.

Dental Education and Examination Committee.

This report was received, and its recommendations adopted, on motions by Sir James Hodsdon (chairman of the Committee). Most of the business reported related to colonial and foreign applications for

registration. Mr. J. Howard Mummery was, by the Council's adoption of the recommendation relating to inspection of dental examinations, appointed as inspector under the Committee.

Public Health Committee.

This report was presented on Saturday, June 2nd, by Sir John Moore (chairman of the Committee). The report was introduced and dealt with in two parts.

1. The first part of the report related to annual returns and interpretation of rules. With regard to diplomas in public health, during the year 1922 369 candidates were examined for the first examination, of whom 271, or 73.44 per cent., passed, and 98, or 26.56 per cent., were rejected. For the second and final examination 391 candidates presented themselves, of whom 277, or 70.84 per cent., were successful, and 114, or 29.16 per cent., failed. During the year the English Conjoint Board granted exemptions to six persons. In two of these cases "candidates were allowed to complete the curriculum in six months by taking out the laboratory course, M.O.H. work, and practical sanitary course in the medical school concurrently, plague duty in India being allowed by the Committee (of the Conjoint Board) to count for the remaining three of the nine months' course of study." The Committee recommended that a communication be addressed to the Conjoint Board inquiring as to the extent and nature of these exemptions, in order to ascertain whether these are in accordance with the Council's rules. Eighteen bodies granted no exemptions during the year.

This part of the report was received without discussion.

2. The second part of the report related to a communication addressed to the President of the Council and signed by the President of the Royal College of Physicians and the President of the Royal College of Surgeons, brought before the Executive Committee of the Council on Feb. 26th, 1923, and by them referred to the Public Health Committee. The letter referred to the resolutions and rules of the Council in respect of the diplomas in sanitary science, public health, or State medicine. In both colleges considerable comment was made concerning the hardship imposed by the new regulations on medical practitioners generally and on colonial and Indian medical officers and officers in the R.A.M.C. particularly. The Committee, in commenting upon the letter, stated (*inter alia*) as follows:—

The whole design of the new Rules is to provide for a diploma, special in character and high in standard, for those who intend to take up an official public health career in the civil communities of Great Britain and Ireland. . . .

The Committee are of opinion that as holders of the Diploma are deemed qualified to take high public positions in Great Britain and Ireland, such instruction taken in any other part of the Empire would not necessarily furnish the candidate with the requisite knowledge for dealing with the problems which arise here.

. . . the functions of a sanitary staff officer of the Royal Army Medical Corps are quite different from those of a civil medical officer of health. Officers in the Navy and Army have to deal with selected lives, under sanitary conditions, at home or abroad, which are very different from those of civil life.

. . . The Committee consider it important that candidates, before entering for the final examination for the diploma, should have the opportunity of gaining clinical experience for at least one year after qualification as medical practitioners.

Various amendments were moved by Sir Humphry Rolleston on behalf of the Royal College of Physicians, but these were not carried. There was some discussion, after which the second part of the Public Health Committee's report (in which the Committee found themselves unable to recommend the Council to agree to suggestions made in the letter from the Presidents of the Royal Colleges) was agreed to by the Council.

Appointment of Registrar.

Mr. Norman C. King was reappointed Registrar.

THE LANCET.

LONDON: SATURDAY, JUNE 9, 1923.

THE TREVETHIN REPORT.

"To consider and report upon the best medical measures for preventing venereal disease in the civil community, having regard to administrative practicability, including cost."

A LITTLE more than a year ago, as a result of correspondence between Sir ALFRED MOND, then Minister of Health, and Lord DAWSON, chairman of the Medical Consultative Committee of the Ministry of Health, the proposal took shape to set up a medical tribunal whose conclusions and recommendations could be submitted to public opinion in reference to the control of venereal disease. The two societies engaged in the solution of these problems—the Medical Society for the Study of Venereal Diseases had not then been formed—concurred in this view, and Sir ALFRED MOND approved the selection by the heads of the medical profession of such a Committee of Inquiry. A committee of 16 expert representatives resulted, which sat with Lord TREVETHIN as chairman, and Mr. T. J. C. TOMLIN, K.C., as vice-chairman, and has now brought in the unanimous report which appears substantially in full in another part of our present issue. Their conclusions and recommendations are, as was so ardently desired, unanimous.

By the terms of their reference the Committee were limited to the consideration of medical measures, but to avoid misunderstanding they record early in the report their conviction that medical measures alone can never operate as an absolute preventive of venereal disease, and that the success of these measures must depend largely upon the coöperation of the community, a coöperation which can only be attained if full knowledge of the nature of the problems to be faced becomes common property. Dealing first with measures for prevention, the report considers these under the two headings of Disinfection by the person himself ("self-disinfection") and Disinfection at the hands of a trained person ("skilled disinfection"). At the outset it is agreed that the prospects of success are less in the case of a woman than in the case of a man. The Committee find no reason to doubt that an intelligent man, furnished with reasonable instructions, could in favourable conditions effectively disinfect himself; nevertheless little direct evidence was presented as to the advisability of introducing public facilities in the civil community. Where satisfactory results were recorded, the Committee found difficulty in determining how far these results were due to the prophylactic methods employed or were influenced by other factors. They do not think that there is any justification for putting obstacles in the way of individuals who desire to procure the necessary disinfectants, although they regard the commercial advertisement of ad hoc disinfectants as a thing to be prohibited. The definite suggestion is put forward that the law should be altered so as to permit properly qualified chemists to sell ad hoc disinfectants, provided such disinfectants are sold in a form and with instructions for use approved by some competent authority, such as the Medical Research Council. From a medical

point of view instruction in self-disinfection given to male persons attending clinics would afford a useful means of educating the community, but the Committee felt that money—known to be limited in amount—spent on a general system of providing facilities for self-disinfection would be less profitably spent than on other measures.

A high testimonial is given in the report to existing venereal disease clinics, which in the Committee's opinion should be encouraged, extended, and improved, for the average medical practitioner is not yet equipped to deal competently with all the cases that come before him. The tendency of patients to cease treatment before completion is not regarded as so serious a difficulty as has been supposed, for by no means all persons who discontinue attendance before completing treatment are infectious, the standard of cure suggested by the Ministry of Health being very high. Notification in itself is regarded as of little assistance unless it is to be supported by a system of compulsory treatment, and, if necessary, detention, but the Committee cannot get away from the hardship of imposing penalties on those who come for treatment while those who make no effort to seek it go scot-free. Pending the general acceptance by the medical profession of a standard of non-infectivity or cure, it would be difficult to apply any system involving notification and compulsory treatment. Improvement of the present clinic system is suggested in the direction of providing more suitable accommodation, greater choice of hours, more hospital beds, hostels for women under treatment, and homes for children. At the same time the report is unanimous that patients who can afford to do so should pay for their treatment at the clinics. Great stress is laid on giving personal instruction and warning to patients attending clinics, a duty which must always devolve mainly on the doctors, but which might be supplemented by trained social workers. In rural areas or districts where clinics are not easily available, the report recommends the setting up of a panel of medical practitioners through whom treatment could be provided. The attention of the authorities concerned is directed towards infective immigrants and seamen, and to the imperfect control of the considerable number of mental defectives who are suffering from venereal disease. A final plea is made for a wide liberty in administration so that local authorities which can make out a case for some special measure should be allowed to carry out their proposal, in order to build up a body of experience that may determine future policy. The tone of the whole report is not unreasonably hopeful, for there is evidence that venereal disease is already substantially declining, and the Committee realise that certain modifications in their views may be called for in the light of important new knowledge of which there are indications.

RICKETS IN VIENNA.

THE main results of the expedition sent by the Lister Institute and the Medical Research Council to Vienna in 1919 under Dr. HARRIETTE CHICK to study deficiency diseases in that unhappy country have been already published in THE LANCET.¹ It was there shown by observations of exceptional precision that the incidence of rickets in children could be determined by dietetic factors, and that fat-soluble vitamins, such as are present in cod-liver oil, and sunlight play important parts. The Medical

¹ THE LANCET, 1921, ii., 842; 1922, ii., 7.

Research Council has now published the full account of these investigations.² It is admirably presented, and deserves the close and critical examination which the ample details render possible. With the general discussions, it provides for human rickets the complement of the volume on experimental rickets by Prof. KORENCHESKY, issued by the Council last year.³

After a general introduction and summary of the recent literature, an account is given, illustrated with many photographs and charts, of the fundamental observations made in Prof. v. PIRQUET's Kinderklinik by Dr. CHICK, Dr. E. J. DALYELL, Dr. HELEN MACKAY, Miss E. M. HUME, Miss HENDERSON SMITH, and Dr. HANS WIMBERGER. It is shown beyond cavil that rickets may be prevented and cured by cod-liver oil, that a diet which in winter will permit the development of rickets may be in summer, with the help of sunlight, adequate to stave it off, and that the disease may be quickly cured by sunlight or the mercury-vapour lamp; they also emphasise the fact, not yet perhaps adequately appreciated, that the chief incidence of rickets is in the first six months of life. The diagnosis of a disease of gradual onset like rickets is in mild and incipient cases bound to be a matter of difficulty, and, to some extent, of differences of opinion. There was a wise agreement to adopt the uniform criterion of X ray appearances, and Dr. WIMBERGER gives a most valuable account of the radiographic changes in rickets and its differential diagnosis by this means. The illustrations are particularly good; being actual prints, not process reproductions, the fine detail can be studied to advantage with a lens, and speaks well for the technical skill with which the photographs were got from rather difficult subjects. Anyone wanting a summary of the appearances of the bones at different stages of the disease would do well closely to examine the frontispiece. Drs. ZARFL, DALYELL, and MACKAY follow with an account of the work done, on a larger scale but in less detail, at the Landes-Zentral-Kinderheim, where mothers as well as infants are received. The results are in general accord with the better controlled data from the Kinderklinik, with the interesting addition that in winter rickets frequently developed in children who were entirely breast-fed, and that this was not prevented by the addition of 12 oz. of butter a week to the mother's diet. Drs. DALYELL and MACKAY discuss also the importance of the various clinical symptoms, and in a short but important section point out that a systematic comparison of the histology of the rib-junctions after death with the signs observable during life shows that a fair number of infants passed as non-rachitic in the wards may really be in an early stage of the disease. In conjunction with the clinical work, Miss HUME made a long series of experiments on rats with different milks. Vienna milk always had a low content in vitamin A, as judged by its capacity to promote growth in rats, and it certainly had little power to prevent rickets in children. Attempts to secure a milk of higher vitamin value by varying the feeding of the cows were not successful, and the value of such milk in the prophylaxis of rickets is an important question which needs an answer. With human milks, observations were difficult, and the results rather inconclusive as regards the correlation between the mothers' milks and the rachitic categories of the children; but clear evidence was obtained that the administration of cod-liver oil to the mother might greatly increase the value of her milk, the effect depending apparently on the nutri-

tional condition of the mother to start with. The paper by the same author showing that ultra-violet light does not replace but only economises vitamin A in the growth of rats is reprinted from THE LANCET;⁴ and the volume ends with a note by Drs. CHICK and DALYELL pointing out that their previous results on the value of cod-liver oil in hunger osteomalacia cannot be explained by the more recent realisation of the influence of sunlight on the growth of bone.

Prof. v. PIRQUET blesses the whole enterprise in a graceful preface. He confesses very frankly that when the inquiry started he did not think much good would come of the attempt to show that rickets was not an infection; he is now persuaded that it is a disease of nutrition and that deficiency of fat-soluble vitamin is an essential cause. To convert the author of the *System der Ernährung* is something. However, *nullius in verba magistri*, and it is possible that everyone will not be convinced by what seem exceptionally clear results obtained in a difficult field. Clinical observation of the order of precision demanded in animal experiments is not easy; it is an individual and temperamental business, and considerations other than the progress of knowledge are constantly cropping up and proving paramount. But in the present instance it has been achieved, and those who have done the work are the first to say that this would have been impossible but for the existence of the splendidly equipped and organised institution over which Prof. PIRQUET presides, and the generous hospitality with which its facilities were put at their disposal. The prime business of the Kinderklinik is not the treatment of the sick poor, which is provided for elsewhere, but to serve the University ideal of teaching and investigation, and it is possible to devote beds over long periods to the use of the children, hardly perhaps ill in any ordinary sense, necessary for the solution of a problem. The need for similar beds in this country is very urgent, and this expression must not be confused with general advocacy of hospital experimentation. Wards full of heterogeneous collections of sick persons fulfil well the primary charitable and the secondary teaching obligations of our great hospitals. They cannot be diverted from their original purpose. But this striking example of what can be done in post-war Austria with beds primarily set apart for investigation may do something to bring about a realisation of the absolute necessity of adding such accommodation to some of our larger teaching hospitals; the number of beds needed is really very few, and the cases to be studied in them would be selected with the double object of giving individual benefit and of strengthening medical resources. Medical research misses its objective by so much as it does not investigate sick people. Laboratories go on increasing without any provision of that to which they are the complement, and laboratory work dominates the field largely because of the difficulties of undertaking serious systematic clinical inquiries in the absence of beds which can be devoted unreservedly to the purpose.

THE CONSTANTINOPLE BOARD OF HEALTH: A VANISHED LANDMARK.

THIS is an era of vanishing landmarks. In the upheaval of the past nine years dynasties have disappeared and empires have crumbled to dust, and in the welter of confusion many a lesser institution has died a silent and almost unnoticed death. Some had served their purpose, and left no tasks unfinished for

² Medical Research Council, Special Report Series, 1923, No. 77.

³ THE LANCET, 1922, ii., 1340.

⁴ THE LANCET, 1922, ii., 1318.

others to complete. Some, on the other hand, were doing work of real value to the world—work which must be continued if the welfare of mankind is not to suffer. To this latter group belonged the Constantinople Board of Health. Created in 1838, that body had for over three-quarters of a century endeavoured to carry out the highly important mandate with which it had been charged by the Powers—that of safeguarding Europe from the incursions of infectious disease from the East through the vast lands that once formed the Turkish Empire. We publish to-day the last section of an historical survey of the work of the Board, from the pen of Dr. F. G. CLEWOW, C.M.G., who was British delegate to the Board since 1900. From this a clear idea may be gathered of the Board's origin and early days, of the wide and complex character of its mandate, of the methods by which it endeavoured to meet its international responsibilities, of its financial resources and of the problems that, as a result of the Board's extinction, must be solved by some other means.

Like many another institution of value to the world, it was in the heyday of its activities and on the eve of making large and costly improvements in its widely scattered establishments, when the thunderbolt of 1914 fell. For reasons explained in Dr. CLEWOW's articles, the financial position of the Board had for some years before the war been a curiously anomalous one. On the one hand, the lazarets and other establishments directed by the Board were in crying need of repair and reorganisation; on the other, the Board possessed a large reserve fund, resulting from an excessive sanitary tariff; yet it was unable to spend any of the reserve in carrying out those repairs, since, under successive international conventions, such expenditure was to be borne by the Turkish Government. In this, as in so many other matters, the latter evaded its obligations, and hence arose the anomalous state of affairs just referred to. A way out of the impasse had, however, been found, by a fresh agreement, under which, as an exceptional measure, over three-quarters of a million sterling was to be spent in repairing the existing lazarets and creating new ones. That that sum was not excessive will be realised when it is recalled that the coasts and frontiers to be defended stretched from the Turco-Persian frontier on the east to the Albanian shores of the Adriatic on the west, and from the Black Sea coasts on the north to the Red Sea shores of Arabia on the south, and that, apart from these coastal defences, the Board was charged with the sanitary supervision of the orthodox Moslem pilgrimage to Mecca and Medina, of the Shiah pilgrimage and carriage of dead bodies to the holy cities of Iraq, and of the newly-opened Hedjaz Railway. In the last nine years before the war complete inspections of all the existing sanitary establishments in these great areas had been carried out; detailed plans and estimates for their reorganisation and the creation of new ones had been prepared; the consent and ratification of all the Powers concerned had been obtained, and, had peace not been rudely broken, the eastern sanitary defences of Europe would in a few years have been put into a more satisfactory and efficient state than they had ever been in before. But the dispositions of God and the propositions of man once again disagreed, and with the outbreak of war these promising schemes were shattered. In the autumn of 1914 Turkey, by a unilateral and arbitrary declaration, put an end to the Capitulations, and soon after eliminated the foreign element from the Board of Health, as being a corollary of the Capitulations. Then Turkey came into the war herself, on what she

fully believed would prove to be the winning side. But her dazzling dreams of a future of conquest, wealth, and independence were rudely upset by events, and four years later she emerged from the war shorn of a vast proportion of her great territories. And with these territorial changes the sanitary problems of the Near East have also changed. The coastal and frontier sanitary defences of Mesopotamia and Iraq, of Arabia, of Syria and Palestine, of Tripoli and Cyrenaica, of the Aegean islands, and of much of the Black Sea, Aegean, and all the Adriatic coasts of European Turkey; the sanitary supervision of the orthodox and Shiah pilgrimages; and that of the Hedjaz Railway have all passed to the authorities of countries other than Turkey, and will no longer be directed by an international body sitting in Constantinople.

The extinction of the Constantinople Board of Health has been formally recognised by the Powers, and the author aptly speaks of his historical survey as an "obituary notice." So far as the sanitary barriers in what remains of the Turkish Empire are involved, the interest of Europe has been reduced almost in the same proportion as that empire's territories have been reduced by the war. But the remnant has a very real and very vital interest for the health of other European countries. The "Straits"—i.e., the Bosphorus, Sea of Marmora, and Dardanelles—are still in Turkish hands, and they are one of the two great waterways by which disease may at any time be brought into Europe from infected, insanitary, and backward countries of Asia. The other is the Suez Canal. The sanitary defences of the Canal are provided for in great detail in the International Sanitary Conventions, and are entrusted to an international body sitting in Alexandria. But under existing conditions those of the even more dangerous Straits are under no international supervision. The necessity of reintroducing some such supervision, in however attenuated a form, is fully realised by the two great international health bodies of Geneva and Paris, and it has been prominently put forward in the Peace Conference at Lausanne, at which Dr. CLEWOW was the British expert delegate for questions of this character. The daily press has already made it known that a compromise has been reached, under which, for a period of years at least, the sanitary defences of Turkey will be under some form of limited international supervision; but we must wait some time longer before the details of the agreement are divulged. That can only be when the terms of the final Peace Treaty with Turkey are made public, and there is reason to hope that the interval of waiting will not now be greatly prolonged.

ROYAL INSTITUTION.—Sir William Bragg has been elected Fullerian Professor of Chemistry and Director of the Davy Faraday Research Laboratory in succession to the late Sir James Dewar.

The Friday evening discourse on June 15th will be delivered at 9 P.M. by Sir Ernest Rutherford, F.R.S., on the Life History of an Alpha Particle from Radium.

HORSHAM HOSPITAL.—On June 1st Lord Leconfield, as the Lord-Lieutenant of Sussex, opened a new hospital at Horsham. The hospital has been erected by voluntary subscriptions to meet the increased needs of the town and district as a war memorial. The cost has been £15,000, three parts of which have already been subscribed. The new hospital takes the place of the original institution erected in 1892 and has 12 beds in each of the two wards, and an emergency ward with six beds, besides accommodation for nurses and staff. It is hoped that the sale of the old building will liquidate the debt on the new institution. A contributory scheme among the working-class population is in operation.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

ON the occasion of the King's fifty-eighth birthday the names of Dr. Hector William Gavin Mackenzie, Senior Censor of the Royal College of Physicians of London, and Prof. William John Ritchie Simpson, C.M.G., a member of the Colonial Advisory Medical and Sanitary Committee, appear in the list of honours as Knights Bachelor, while Major-General Owen Edward Pennefather Lloyd, V.C., C.B., retired pay, Colonel Commandant, R.A.M.C., is promoted to K.C.B. In the same Order Surgeon Rear-Admiral Joseph Chambers, C.M.G., becomes a C.B., as does also Colonel Walter Holland Ogilvie, C.M.G., I.M.S., Assistant Director of Medical Services, Presidency of Assam District, India. Lieut.-Colonel Asher Leventon, I.M.S., Superintendent of the Campbell Medical School and Hospital, Bengal; Lieut.-Colonel Thomas Hunter, I.M.S., Civil Surgeon, Lucknow, United Provinces; and Lieut.-Colonel Robert McCarrison, I.M.S., have been awarded the C.I.E. In the Royal Victorian Order Mr. Henry Linnington Martyn, F.R.C.S. Eng., and Mr. Francis Jeune Willans, M.R.C.S. Eng., become Members of the Fourth Class, and in the Order of the British Empire Major and Brevet Lieut.-Colonel Ralph Bignell Ainsworth, D.S.O., R.A.M.C.; Lieut.-Colonel Irvine Davys, I.M.S., Flight-Lieut. Christopher Thomas O'Neill, Royal Air Force, and Dr. Benjamin William Quartey-Papafio, Member of the Legislative Council of the Gold Coast Colony, formerly Assistant Colonial Surgeon, are made Officers, and Dr. (Miss) Agnes Henderson, Central Provinces, and Captain Antonelli Francisco Bartholomeu Saldanha, I.M.S., Members of the Order. Mr. Oguntola Sapara, L.R.C.P. Edin., medical officer, Nigeria, has been made a Companion of the Imperial Service Order. The list also includes the names of Mrs. Lilian Agness Starr, matron in charge of the C.M.S. Mission Hospital, Peshawar, North-West Frontier Province, who has been given a bar to the Kaisar-i-Hind Medal, and Miss W. J. Meiklejohn, nursing superintendent at the General Hospital, Rangoon, who receives the medal, and Miss Winifred Mary Aldridge, R.R.C., senior nursing sister, Queen Alexandra's Military Nursing Service for India; Mrs. Rose Lilian Vincent, M.B.E., who become Officers of the Order of the British Empire, and Mr. Claude R. Grice, Personal Assistant to the Director of Health Services, Iraq, and Alice Mary McClure, acting matron of the Mosul Civil Hospital, Iraq, who become Members of the Order. We offer our hearty congratulations to all who have thus been honoured.

THE WORKMEN'S COMPENSATION BILL.

SOME weeks ago we commented upon the judicial incrustations which have been allowed to restrict the award of workmen's compensation where the "accident" is of the nature of disease. The Government's new Workmen's Compensation Bill does something to widen the basis of awards. It proposes *inter alia* that accidents resulting in the death or serious and permanent disablement of a workman shall be deemed to arise "out of and in the course of" his employment, notwithstanding that he acted in contravention of any statutory or other regulation or of any orders given by his employer or without instructions from his employer, if such act was done by the workman for the purpose of and in connexion with his employer's trade or business. Medical practitioners will be interested in two other provisions included in the Bill. One is the proposal that in every factory (unless there is already a proper ambulance room with arrangements for the immediate treatment of injuries) there shall be a first-aid box or cupboard under the charge of a responsible person

who shall always be readily available during working hours; where there are more than 150 persons employed, there is to be an extra box or cupboard for every additional 150 employees. The other proposal of interest concerns medical referees. Under the existing law, when employer and workman cannot agree as to the workman's condition or fitness for employment, the registrar of a county court may refer the matter to a medical referee on payment of a fee by the applicant. It is proposed to do away with the fee and to allow a reference on the application of either side, subject to appeal to the judge. Reference to a medical referee at present also takes place (under section 8 (1) (f) of the 1906 Act) if employer or workman is aggrieved by the action of a certifying or other surgeon in giving or refusing a certificate of disablement or in suspending or refusing to suspend a man from work. The Bill proposes that the medical referee when deciding the matter shall also give a certificate (which shall be conclusive) as to the condition of the man at the time when he examines him.

This Government Bill, which received its second reading on May 30th, is to be distinguished from the more comprehensive but politically less practicable Workmen's Compensation Bill introduced by Mr. J. H. Thomas on behalf of the Labour party. The main difference between the two is that the latter is a complete legislative embodiment of the recommendations of the Holman Gregory Committee, while the former is not. The Government Bill, for example, ignores the Committee's recommendation of compulsory insurance and of the supervision by the State of rates of premium, though it does include the Committee's suggestions as to the waiting period and as to the extension of the Acts to shore fishermen, London taxicab-drivers, golf-caddies, and so on. The Bill is not the complete consolidation of the law for which we had hoped. Perhaps the law is not yet stable enough. We seem still to be experimenting with a novel category of legal procedure in which, at any rate from the employer's point of view, liability is not in any way based upon fault. We observe that in treatises such as the useful and well-documented survey of Accident Insurance by Mr. Baker Welford, which has just reached us,¹ learned authors are cautiously confining themselves to the search for fixed principles rather than to the textual interpretation of statutes which as yet resist crystallisation.

THE ODOUR OF THE URINE.

SINCE 1919 Dr. Emilio Pittarelli has been engaged in investigations with the object of determining to what substances the odour of the urine is due. Most text-books of physiology or clinical chemistry have hitherto been very vague on this matter. Nessler's reagent, which gives a red-brown precipitate as a test for ammonia, has been found also to give a greenish-yellow precipitate with normal urine previously purified by a mixture of corrosive sublimate and bicarbonate of soda. When such urine is distilled an unknown, or imperfectly known, substance begins to volatilise at 60–70° C., but completely leaves the urine only at the boiling point. The distillation must be made in an acid medium to prevent preformed ammonia and that formed during boiling passing into the distillate. Phosphoric acid is preferable to obviate the impurities met with in hydrochloric and sulphuric acids. The distillation is complete when it amounts to at least one-quarter of the urine. The chief characteristics of the distillate are—a limpid colourless fluid of intense urinous odour, neutral to all reagents. It is not precipitated by alkalis or acids nor with the bicarbonate and sublimate mixture; it does not react with Fehling, nor give the diazo-reaction in neutral or acid media; no apparent change takes place with salts of silver, cadmium, iron, lead, mercury, or zinc. With Nessler's

¹ The Law Relating to Accident Insurance. By A. W. Baker Welford, Barrister-at-Law. London: Butterworth. 1923. Pp. 652 and 54. 35s.

reagent it gives the greenish-yellow precipitate, similar to that given with many other substances, such as alkaloids, amides, all amines, organic ammonias, aldehyde, and methylene derivatives. Nessler's reagent is very sensitive to ketones and particularly to acetone, but the presence of the latter may be excluded as being the factor in the precipitate, for it has no odour, and its precipitate is milky-white instead of greenish-yellow; moreover, the other reactions for acetone, such as acetol, iodoform, and nitroprussiate, do not occur. Dr. Pittarelli¹ concludes from the result of his experiments that there is a close relation between the odour of the urine, the distillate, and the precipitate, and that there is a volatile body in normal urine resembling ketone, but different from ordinary acetone, precipitated by Nessler's test, and that it is to this substance that the characteristic odour of the urine is due.

RETIREMENT OF SURGEON-GENERAL SIR GERALD GIFFARD.

AFTER nearly 35 years' service, Sir Gerald Giffard, Surgeon-General with the Government of Madras, has arrived home on leave, preparatory to retirement. General Giffard's name will always be associated with the reconstruction of the Government Maternity Hospital, and the building of the School of Midwifery in Madras, which last is known as the "Giffard School." During his strenuous years in the Maternity Hospital and also during his tenure of office as head of the medical department in Madras, he has been the keen champion of the nursing profession. During his term of office the Madras Nurses' Association was formed; the members of the Association recently entertained General Giffard at an "At Home," held in the Y.W.C.A. grounds. In his reply to a tribute of praise paid to him by Mrs. Symons, President of the Association, Surgeon-General Giffard said that he had welcomed the formation of the Association, but that much yet remained to be done for the nurses. The Madras Government had recently passed an order that only qualified nurses should be employed in State hospitals; this meant that unqualified nurses would no longer be able to rise to the higher ranks of the nursing profession. The Government was also arranging for pension and provident funds for their nurses, and the papers connected with this subject were now before the Secretary of State for India. We congratulate Surgeon-General Giffard on the valuable work for maternal welfare which he has been able to initiate, the results of which are as yet only dimly seen.

BOWEL DISEASE AMONG MINERS IN THE TROPICS.

WE recently printed² an abstract of the research programme of the School of Tropical Medicine at Calcutta, from the pen of Major Robert Knowles, I.M.S., professor of protozoology in the school and its secretary during the critical early days of its existence. The annual report for the year 1922 now reaches us, containing additional information on the work of the school and of the Carmichael Hospital for Tropical Diseases, and, amongst other things, an account of the inquiry into the causes and prevalence of bowel diseases in colliery districts—an inquiry which was financed by the Indian Mining Association. The investigation was entrusted to Captain G. C. Maitra, I.M.S., who forthwith started to find out the number of bacillary dysentery carriers in hospital patients. No success attended his efforts during the hot weather, but with the advent of the cold season the proportion of faecal specimens giving an alkaline, or neutral, reaction became larger, but even then no dysentery organisms were isolated from faeculent specimens. The cultural results of blood and mucus

stools were not satisfactory; 15 samples were examined and typical organisms, once a Shiga bacillus and once a Flexner bacillus, were isolated from two only. Both these were from early cases of the disease which had developed locally. Success in recovering dysentery organisms depends mostly upon the freshness of the sample of stool, even in early cases of the disease. Sixty blood samples were examined for agglutinins by the macroscopic method, and out of these 17 only gave a higher titre than 1:40, and mostly with the Flexner organism. Ascitic fluid was also examined for antibodies in eight cases, and it was found that this fluid inhibited the growth of the dysentery bacillus; the reason for this inhibition does not seem to be sufficiently clear. The field work was conducted at Dhanbad, when 1200 samples of faeces, 11 samples of water, and three batches of house-flies were examined, and it was found that the majority of cases of dysentery among the miners are bacillary in origin. The general conclusion is that monsoon prevalence of bowel diseases in the coal-fields is to be attributed to polluted water-supply, while there is also a probable correlation between bowel diseases in miners and ankylostomiasis.

THE FUTURE OF MEDICAL BENEFIT.

TIME is running out in regard to the panel settlement, for the present compromise lasts only another six months. Panel committees have been fully instructed in the views and temper of their constituents, and, as we go to press, their representatives are meeting at Westminster to decide on a course of action. At this juncture it may be of interest to set down the position of medical benefit as seen by the *National Insurance Gazette*, which sums up thus in a recent leading article:—

"A good number of doctors are giving a thoroughly good service; others are overpaid; still others are giving nothing better than the old club practice, and the small residue—well, no respectable 'club' would have contracted with them. That is the problem of the panel service, as we see it. We wish we saw the solution as clearly."

No doubt the panel system as it stands does allow a good deal of latitude to the so-called black sheep for whom the only effective and speedy remedy is disciplinary action by the medical profession itself. And this view is spreading, for a prominent official of a large friendly society is reported as saying:—

"In my opinion the doctors themselves, through the British Medical Association, could do far more to improve the service than it is possible either for the Ministry of Health or the insurance committees to do. By their own Council they could bring to book and deal effectively with any doctor who failed in his duty to his panel patients."

There would appear to be appropriate administrative machinery in existence for this purpose. In conjunction with the Insurance Acts Committee the local panel and medical committees might be empowered to deal with irregularities which presumably come to their knowledge at a very early stage, while the Ministry of Health might enlist the services of panel committees to a much greater extent than is done at present. In this way the "thoroughly good service" which is the mainstay of medical benefit would not be overshadowed—quite unjustly and out of all proportion—by the worser service.

MEGALO-URETER.

At a recent meeting of the American Association of Genito-Urinary Surgeons, Dr. John R. Caulk,¹ of St. Louis, remarked that anomalies of the ureter have ceased to be autopsy curiosities and have acquired a very important clinical position since the development of scientific urology. His paper, which includes the report of a personal case, deals with variations in the calibre of the ureter which hold an intermediate position between irregularities in number, which are the commonest, and aberrations of insertion, which are the rarest. The most frequent type of change in

¹ La Riforma Medica, xxxix., May 14th, 1923.

² THE LANCET, April 7th, p. 728.

¹ Journal of Urology, April, 1923.

ureteral calibre is enlargement. Abnormal dilatations are fairly frequent and are usually attributed to congenital strictures or valves, most of which are situated near the bladder and in most instances are associated with a marked enlargement of the ureters. In a few cases the stricture area is very extensive, the ureter being replaced by a fibrous cord. The causes of ureteral enlargement are to be found in (1) obstruction, (2) primary alterations in the ureteral wall itself, and (3) a combination of these two causes. Whatever the cause of the obstruction may be, the effects upon the ureter are the same, consisting almost always in the production of a thin-walled tortuous tube varying in calibre from that of a pencil to that of the small intestine. An admirable illustration of a dilated and tortuous ureter appears in Sir John Bland-Sutton's lecture at the front of our present issue. Dr. Caulk notes that the wall of these dilated ureters often shows valve-like folds. Primary enlargement of the ureteral wall may be congenital or acquired. Apart from tuberculosis, changes in the ureteral wall due to inflammation are rarely sufficient to cause considerable changes of calibre, the most constant change being irregularities of outline. In cases hitherto recorded dilatation of the ureter has usually been associated with dilatation of the renal pelvis, ranging from moderate distension to enormous sacs completely destroying the parenchyma. Dr. Caulk now reports a case in a woman, aged 32, which was remarkable for the fact that enormously dilated ureters were not accompanied by a corresponding dilatation of the renal pelvis, ureteral obstruction, or proportionate disturbance of renal function. Marked improvement followed an extensive cystoscopic incision of the uretero-vesical valve. Dr. Caulk has given the name of megalo-ureter to the condition present in his case, as he is inclined to believe that the ureteral enlargement represents a defect in the ureteral wall of a congenital nature, comparable to the condition in the large bowel, especially the sigmoid, which is known as Hirschsprung's disease or megacolon.

NEBULOUS CONCEPTIONS OF DYSPEPSIA.

THAT comfortable sense of complete and well-rounded-off knowledge with which the medical student leaves his hospital is seldom retained for long, and the vagaries of the gastro-intestinal tract alone soon leave most practitioners convinced of the modesty of their diagnostic attainments. No one who has visited the Bispebjerg Hospital in Copenhagen can have formed anything but a high opinion of the efficiency of its staff, and yet, as far as the diagnosis of dyspepsia is concerned, its records show that it is the exception rather than the rule for the symptom of dyspepsia to be tracked down to some definite morbid state. According to Dr. E. Meulengracht,¹ the Department B of this hospital treated between 300 and 400 cases of dyspepsia in 1921, and in addition to the usual functional tests, X ray examinations were carried out in most of these cases. Yet, in more than half of them nothing was found to account for the dyspepsia, and in from 60 to 70 per cent. there were no definite signs to confirm the patients' symptoms. And in the remaining 30 to 40 per cent. the signs found were often not sufficiently distinctive and pathognomonic to be of much diagnostic importance. They were, in fact, so lacking in distinctive instructiveness that they left a large choice of diagnoses suitable for the tastes of various physicians. Dr. Meulengracht would seem to have taken an almost whimsical interest in betraying the lack of accurate knowledge with which we are still afflicted in this matter. He has published the diagnoses made in 1920 by four communal hospitals in Copenhagen, all of which admitted cases of dyspepsia. The first hospital treated 161 such cases, 86 being given the label of "ulcer" and 21 that of "constipation." "Gastritis" figured in 16 cases and "colitis" in 10.

Only in 1 case had the non-committal diagnosis of "dyspepsia" been made. The second hospital had treated 124 cases, of which as many as 21 were given this non-committal label. There were only 7 cases of "constipation," 62 of "ulcer," and 7 of "gastritis." The third hospital had 282 cases of dyspepsia, and while the second hospital had only 6 cases of "colitis," the third hospital had 72. It had as many as 48 cases of "gastritis." The fourth hospital had 183 cases of dyspepsia, and in as many as 86 the label given was "dyspepsia." The label of "gastritis" was given to only 2 cases, and of "ulcer" to only 37. The fact that in one hospital 54 per cent. of the cases of dyspepsia were labelled as "ulcer," while only 20 per cent. were given this label in another hospital, suggests that at present the labelling of dyspeptic patients is a random and haphazard process which even in an up-to-date hospital is at the mercy of transient fashions, the proclivities and fancies of the individual physician. The labels—"gastric atony," "ptosis," "gastritis," "achylia gastrica," "ulcer," "enteritis," "colitis," "constipation," and many others seem still to be distributed with the impartiality of ignorance.

PUBLIC HEALTH INTERCHANGE.

THE Health Organisation of the League of Nations aims at establishing closer relations between the health services of different countries and at bringing about mutual understanding between national health administrations. In October, 1922, with the aid of a generous grant from the Rockefeller Foundation, amounting to \$60,000 annually for three years, the Health Committee started a system called "International interchange of public health personnel," although the title is misleading in so far as it implies that individual officials actually change places. In practice the system, as it has been tried hitherto, is an arrangement by which a number of selected medical officers of health, and other medical men holding appointments under a central or local public health authority, take part collectively in an arranged course of lectures, demonstrations, and practical work in a foreign country. The duration of the course is usually three months or less, the period being passed in one country or in two countries as may be arranged. We learn from a report presented by Sir G. S. Buchanan to the League's Health Committee at the session which began its sittings in Paris on May 26th, that four kinds of courses are contemplated or have been actually tried: (1) collective "general" courses dealing with public health arrangements as a whole and intended to be applicable chiefly to the senior members of the public health service who are concerned largely with administration; (2) collective "specialist" courses dealing with a particular public health subject such as tuberculosis or maternity and child welfare; (3) "specialist" courses for bacteriologists engaged in laboratory work on public health subjects; (4) individual arrangements for particular public health officers from distant countries who may desire to study public health work either from the general or special point of view.

The courses actually completed or at present in being are: (1) a "general" course of two months' duration from Oct. 9th to Dec. 17th, 1922, in Belgium and Italy; (2) a "general" course of three months' duration from Feb. 25th to May 20th, 1923, in Great Britain and Austria; (3) a "specialist" course now proceeding (from May 21st to June 12th) on methods of dealing with malaria in Italy. Arrangements have also been completed for the visits of public health bacteriologists to the laboratories of other countries than their own, and preparations are in progress for a "general" course in the United States of America. Altogether some 83 officers from 24 different countries have taken part. As a means of building up habits and traditions of co-operation and mutual help between the health officers and administrations of the countries concerned the system has much to commend it.

¹ Ugeskrift for Laeger, May 10th, 1923.

THE DISCIPLINARY FUNCTIONS OF THE GENERAL MEDICAL COUNCIL.

THE session of the General Medical Council which has just risen was largely occupied by the hearing of penal cases. Brief accounts of these cases are published in another column, and the nature of the charges and of the results merit a little consideration. In the first instance, there were 12 cases, affecting 13 individuals, but only two erasures followed the hearing of the charges, and in both these cases previous criminal convictions had been registered. Considering the size of the constituency and the various directions in which disciplinary action may have to be taken, the number of suggested infringements of the professional code is very small. Three of the cases dealt with irregularities in the issue of certificates, and although the names of none of the four persons concerned were erased, the offenders met with severe official reproof. This is not to be wondered at: the powers inherent in the medical certificate are so important and far-ranging that the State is right to expect from those who are privileged to grant these documents the fullest sense of responsibility and the maximum of accuracy. There were two cases of "covering," one of which was reported by the Dental Board, the other of which took notice of the relation between a general practitioner and an uncertified midwife. In both cases judgment was postponed in order to allow the practitioner to set in order his professional behaviour, and the leniency is reasonable when it is remembered what removal from the Register may mean. It will give the opportunity to the practitioners to consider what "covering" implies; the offence proposes either to defeat the law of the land, or to gain undue advantage over a professional colleague observing the proper restriction. Of two cases of advertising, in one the facts were not proved, and there is no offence, of which the Council has to take official cognisance, which requires more accurate scrutiny. The charge of advertisement is so easily made, but the responsibility for the undue publicity can so rarely be fixed. In many cases where there has been an easily comprehensible feeling that professional ethics have been ignored, the supposed offender has been entirely innocent of the mischief.

VOLUNTARY HOSPITALS AND THE KING'S FUND.

VOLUNTARY hospitals have shone so brightly during the past week that it is only the confirmed pessimist who can see therein the last flickers of an expiring system. The King and Queen have laid foundation-stones of new sections of University College Hospital which were, until the Rockefeller gift, quite beyond the reach of legitimate hope. St. Bartholomew's Hospital has begun an octocentenary celebration modestly designed to carry on the tradition for another 800 years. The British Hospitals Association has held its annual conference at Sheffield, and the brief extracts from some of the communications which appear at the end of this issue will serve to show the varied interest. A study of the daily press reveals the gratifying fact that hospital administration now interests a large public. At the annual meeting of the General Council of King Edward's Hospital Fund for London, held in the House of Lords on June 4th, the Prince of Wales, who presided, referred to the Combined Appeal on behalf of the voluntary hospitals as the principal business of the year. That appeal has been a success, and the reasons for this were given by the Prince. First of all, the cause was good, while the voluntary system makes an almost universal appeal to our sympathies; secondly, the appeal was well organised; and thirdly, the organisation had a good personnel. But, as the Prince pointed out, although the hospitals have been relieved from the crushing weight of the deficits of the years immediately following the war, the problem is not completely solved, for the hospitals have both to maintain their position and to improve it. Lord Revelstoke, the hon. treasurer, said that the total receipts

were £481,640, the total distribution amounting to £413,214. The sum reported as being available for the special distribution by the King's Fund was £365,000. This includes all gifts earmarked to hospitals co-operating in the appeal. It does not include the sum of £11,268 earmarked to the King's Fund and distributed in its ordinary distribution for 1922. Nor does it include £7536 earmarked to other central agencies, to hospitals for an agreed share of special events, and to non-co-operating hospitals; nor £4411, the value of equipment handed to hospitals and central societies; nor £25,000 reserved, at the desire of donors to that amount, for assisting the promotion of schemes for raising permanent income for hospitals by means of mass contributions. A list of the hospitals receiving awards under the Combined Appeal will appear in a future issue.

PASTEUR CELEBRATIONS AT PARIS.

THE "Fêtes du Centenaire de Pasteur" were inaugurated on May 24th by a brilliant evening reception held by the President of the Republic at the Palais de l'Elysée. Next morning delegates of foreign governments and representatives of foreign universities and learned societies found their way by the well-known entrance from the Rue Dutot to the Institut Pasteur. For those who were not familiar with the route admirable arrangements had been made by the municipal authorities whereby those invited found themselves at various "points de concentration." Here motor-buses were provided and visitors were transported in good time for the reception by Dr. E. Roux, director of the Institut. Roux, bearing the impress of long and patient suffering on his countenance and general aspect, stood out as the same courteous and sympathetic gentleman as ever. After the reception in the grand amphitheatre, the delegates and representatives arranged amongst themselves who should speak at the subsequent ceremonies, and formal proceedings gave place to pleasant intercourse and the reunion of old acquaintances. This occasion will be remembered by many as one of the most agreeable gatherings to which the whole elaborate programme gave rise, and to many brought back a vista of rich memories of the days of Pasteur and his colleagues at the Institut. A great album was provided for the signatures of the guests and to each was presented a special centenary medal of Pasteur and a print of the master himself. All this was but the prelude to the great "Cérémonie à la Sorbonne." At 3 p.m., in the grand amphitheatre, just before the grand ceremony, the unveiling of a plaque commemorative of the famous meeting at the Sorbonne of Lister and Pasteur took place, and a print reminiscent of this historic event was presented to each delegate. In the quadrangle were grouped delegates and representatives garbed, many of them, in their varied academic robes. Members of English and Scottish universities were more or less conspicuous in red gowns. When the ambassadors and other high dignitaries had taken their places Mr. Alexandre Millerand, President of the Republic, took the chair, and the band of the "Garde Républicaine" struck up "La Marseillaise." Mr. Léon Bérard, Minister of Public Instruction and Fine Arts, in stirring words recalled the works of Pasteur and paid a tribute to the beneficent influences and far-spread practical application of the results of his labours. Then came the turn of certain foreign delegates. Prof. W. H. Welch, of Johns Hopkins University, spoke first and other delegates read their addresses in turn. Sir Charles S. Sherrington, P.R.S., read the address from the Royal Society of London; others who followed presented their addresses. Mr. Strauss, the Minister of Hygiene, then spoke with eloquence. So ended a day in praise and in memory of Pasteur.

Saturday, May 26th, brought more ceremonies. At 10 a.m., this time at the "Ecole Normale Supérieure," Rue d'Ulm, a reception was held by Mr. Gustav Lanson, the director, and where the guests passed through the "Cabinet de Pasteur," and an hour later, at the

adjacent Rue des Feuillantines, a plaque commemorative of the house where Pasteur lived as a student was inaugurated by the President of the Municipal Council of Paris. This part of the programme had a double object, and was intended to commemorate two distinct periods in the life of Pasteur. Between 1838-43 he studied at the Ecole Normale; from 1843-49 he was administrator and director of scientific studies. The afternoon was partly taken up by a reception at the Hôtel de Ville. This particular Saturday was also notable for the celebration of the seventy-fifth anniversary of the foundation of the Société de Biologie, founded in 1849. By way of emphasising the importance and high standing of this well-known Society, the Societies of Biology of Bordeaux, Marseilles, Nancy, Petrograd, Lille, Barcelona, Strasbourg, Lyons, Buenos-Aires, Athens, Belgrade, Roumania, Portugal, Belgium, Denmark, Spain, Brazil, and Sweden sent delegates to pay tribute to the parent society in Paris. Shortly after 9 A.M., with the genial and eloquent Prof. Charles Richet in the chair, addresses were presented by these daughter societies. Prof. Richet first addressed the audience, which filled the rather sombre meeting-place, and then business started. Prof. A. Brascet, of Brussels, gave an admirable address entitled *Génération et Fécondation*, which merits special attention. By way of distraction, perhaps, members and delegates in the afternoon were invited to ascend to the third platform of the Eiffel Tower. The true Pasteurians were free on Sunday, but in their honour a gala evening at the Opera and Théâtre Français was provided. Those invited could choose opera or theatre. Not so the ardent biologists. Summoned again on Sunday for 9 A.M., they devoted their energies to the Physiological Action of Potassium and Calcium, on which subject Prof. H. Zwaardemaker gave a most interesting contribution. There was still no rest for the biologists. In the afternoon a "promenade-conférence" to the Marais, one of the most interesting quarters of old Paris, replete with ancient monuments, was undertaken by many of the foreign delegates.

Monday, the 28th, brought its due quota of visitations and attractions. At the Palais de Versailles, in the Galerie des Batailles, there was provided, just after midday, a sumptuous banquet for several hundred guests. The table of honour was arranged in the middle of the length of the enormously long room, and right and left 60 tables in all for the guests. The cover of the menu was well designed. It showed Pasteur with his well-known cap on his head, his face in profile, and suitable inscriptions below. The guests were conveyed back to Paris by special train. The biologists on Monday assembled to listen to a communication by Prof. Cantacuzène on the Problem of Immunity amongst the Invertebrates. On Tuesday, May 29th, Mr. Gaumont presented his film of the life of Pasteur at Place Clichy, and in the afternoon a garden party was held by the Institut de France at Chantilly. On May 30th those who were invited proceeded to Strasbourg, where, on May 31st, the inauguration of the Monument and Museum of Pasteur and the Exposition d'Hygiène were inaugurated.

WALLER MEMORIAL FUND.—It has been decided to create a research fund in connexion with the London (R.F.H.) School of Medicine for Women as a memorial to the late Prof. A. D. Waller and Mrs. Waller. Already £1100 have been promised. The hon. secretaries of the Fund are Prof. Winifred C. Cullis and Prof. J. Macdonald, and the hon. treasurer is Prof. J. Mellanby, of St. Thomas's Hospital, London, S.W.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—On June 2nd H.R.H. Princess Mary, Viscountess Lascelles, visited the school to distribute prizes and certificates for the past year's work. Princess Mary was received by Miss Aldrich-Blake, Dean of the school, who in the course of a short address recalled the fact that in the autumn of this year the school would reach its fiftieth anniversary. During the half-century over one thousand women had passed through the school, over seven hundred of them being now in the United Kingdom.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXIII.—THE TREATMENT OF CYSTITIS.

It is assumed in these notes that stricture, prostate, and nervous disease have been excluded, that the bladder has been explored for the presence of stone, growth, or other primary lesion, and the urinary tract for the possibility of a complicating pyelitis, prostatitis, or urethritis. Promiscuous medication in the presence of any of the above is not likely to be successful. These precautions having been taken, alternative methods of medication are open for adoption in any given case, and these may be designated (a) the alkaline, and (b) the acid treatment. Cases which will be improved by the one may be injuriously affected by the other, the indications for either depending largely on the nature of the responsible organism. Whilst these are being investigated, treatment should be started. A useful rough guide is the reaction of the urine. In an acid urine the pathogenic organism will probably be *B. coli*, gonococcus, or the tubercle bacillus; any of these is suitably treated by alkalis. All the remaining organisms prefer an alkaline medium, though a few may tolerate an acid one. The urine examined must have been recently passed, and the patient must not have taken any drugs which would exert an influence in this respect. The possibility of examining during the alkaline tide must also be considered.

Elimination of Organisms from an Acid Urine.

Taking the acid living types first, the gonococcus may generally be excluded by the two glass test and by the history; the tubercle bacillus by a careful consideration of the history, onset, &c.; in each case the recovery of the organisms should be attempted. The *B. coli communis* remains; here the first step is smartly to render the urine alkaline; the value of this manoeuvre is often striking. For this purpose potassium and sodium acetate or citrate are commonly used in doses of 10 to 30 gr. A greater degree of alkalinity can be obtained by using sod. bicarb. and a combination of the drugs is to be recommended.

The patient is too often allowed to rise from bed too soon. A relapse frequently follows and a return to bed and a second early rising may cause a further relapse. I believe in a prolongation of the initial confinement to bed for a period of a week or ten days after the temperature is normal and the urine has cleared, and when the invalid is allowed to get up it should only be for a short time at first; he should be well protected from cold.

Following a few days on alkaline treatment, a sudden change must be made to the acid regime, combined with the exhibition of hexamine. Alkalies are not curative but merely ameliorators of the symptoms. It is, indeed, proved that the inhibitory effect of an alkaline urine on the growth of the *B. coli* is quite inconsiderable (Jordan). The hexamine is brought into action as the symptoms are abating, in order to kill off the infection. It frequently causes a temporary increase in discomfort and urinary frequency, together with more mucus in the urine. Of this the patient should be forewarned, so that he will not suffer disappointment or suspect relapse. The change over should antedate the rising from bed by a few days.

Elimination of Organisms from an Alkaline Urine.

The first step in the treatment of alkaline cystitis is invariably an attempt to render the reaction of the urine acid. This is not always possible, but to reduce the degree of alkalinity is in itself beneficial to the patient. Much the most suitable drug for this purpose is acid sodium phosphate, the salt responsible for rendering the normal urine acid. It is given in doses of from 10 to 30 gr. If there is difficulty in achieving

an adequate acidification by such means, an adjuvant action may be obtained with ammonium benzoate (10 gr. t.i.d.). These two drugs are the only ones which have any marked effect in increasing urinary acidity. All the mineral acids, boric acid, and the organic acids may be discounted.

The degree of acidification possible is noted by the medical man, and the subsequent treatment may be considered according as it is found possible, or otherwise, to obtain a distinctly acid urine.

1. *Where an Acid Urine is Obtained.*—This group gives gratifying results in practice, because we can employ the formaldehyde antiseptics, of which hexamine is the most important. It is a compression product of ammonia and formaldehyde, and it is solely by the liberation of the latter in the urine that it obtains any antiseptic action. This action is proportionate to the quantity of formalin liberated and to its urinary concentration. Further, the liberation of formalin is only accomplished in acid urine, and the degree of acidity must be fairly high before it can be released. Ignorance as to how the drug acts must be responsible for its prescription with pot. cit. or other alkali, or in its being given with an alkaline urine. A more insidious mistake occurs when a patient suffers from some coincident trouble such as bronchitis or dyspepsia, both of which are common in cases of prostatic disease. In either case alkalis may be prescribed without their effect on the liberation of hexamine being considered. Occasionally a patient exhibits an idiosyncrasy to hexamine which generally shows itself as strangury or hæmaturia. I have seen a case in which a small dose has been followed by acute dermatitis and conjunctivitis. Always commence, therefore, with small doses (5 gr., t.i.d.) to exclude idiosyncrasy and increase rapidly to large doses of 15 or 20 gr. t.i.d. Better a powerful action for a short time than a feeble action spread over a long time (Thomson Walker). One of the most valuable functions of hexamine is prophylaxis especially following instrumentation.

2. *Where an Acid Urine cannot be Obtained.*—The problem here presented is much more difficult than the preceding one. The first move should be to get the urine as near to acidity as possible in order to diminish urinary decomposition and hinder the growth of organisms. This reduction of alkalinity may be regarded as an end in itself; it is obtained by means of the same agencies as have been discussed above. Various attempts have been made to find a compound capable of liberating formalin in an alkaline medium, but hitherto without success—at any rate with any degree of alkalinity obtainable in urine. Thus we have to resort to other drugs. Of these probably the best is ac. boric (Anson Jordan). Salol is also a drug of considerable value. Proflavine and acriflavine have recently been introduced as urinary antiseptics and are on trial. They are given by mouth in capsules in doses of 0.05 to 0.1 g. They are excreted in the urine and their antiseptic properties are best developed when it is alkaline. Present experience indicates that they have considerable value. This group of cases is the one which is generally the most suitable for local applications such as lavage.

Local Treatment.

Local treatment may be either by lavage or by installation. Lavage is a valuable adjuvant in many cases, but the indications should be carefully weighed. It should never be used in acute cases, nor in cases where the tubercle bacillus has not been definitely excluded. Where it is definitely proved that there is only one responsible organism the surgeon must carefully consider whether it is wise to run the risk of introducing secondary contamination, which may be more difficult to eradicate than the original offender. Lavage should not be instituted until other methods have been given a reasonable chance. It is chiefly valuable for severe chronic cases infected by multiple organisms; such patients have usually undergone previous instrumentation and have often alkaline urines.

In the male lavage may be done by the catheter and funnel, but is often best performed by the method of Janet, especially in chronic cases, just as it is so often practised in the treatment of a deep urethritis. An intelligent patient is easily taught to undertake this treatment himself, with the advantage that it can be done several times daily. A small quantity of the antiseptic fluid may be left in the viscus at the conclusion. In the female a rubber catheter and syringe or funnel will be employed. Never employ a hard catheter, as the vesical mucosa may be thereby injured. Washing and re-washing should continue until the fluid returns clear. In cases where the bladder is very sensitive care should be taken never to over-distend. Equally important is the rule not to allow such a bladder to be completely emptied during lavage—about 2 oz. should be left in prior to re-filling. Successive treatments may be shown to give increasing distension, and occasionally the making of a chart to demonstrate this will encourage the patient. The use of novocain, 2 per cent., or stovain, 4 per cent., will alleviate any pain from this form of treatment. The most useful wash is silver nitrate 1/2000 to 1/8000.

Sundry Further Points.

Diet and Forced Diuresis.—The diet in the early stages should consist of light nourishing fluids, especially milk, milk and water, and barley water. Actually one of the most valuable remedies at our service is forced diuresis. The patient should take at least a tumbler of fluid hourly during the early stages. Caffeine may be combined with forced drinking in order to stimulate renal activity. These large quantities of fluid act mechanically, clearing the mucosa of the bladder from pus and organisms; they also keep the urine dilute and thus bland. When the acid treatment is being administered alkaline gaseous drinks should be avoided, though during alkaline medication they are of considerable value.

As time proceeds diet will be cautiously strengthened, but so long as any evidence of cystitis remains it will be advisable to withhold any article of diet which may act as an irritant to the urinary tract. In patients under careful clinical supervision a close parallelism will be observed between the diet and the inflammatory deposit in the urine.

Climate.—The bladder is one of the most chillable organs in the body, reacting very sensitively to variations of temperature, and relapses are frequent during convalescence from the effect of cold. Chronic patients, especially sufferers from tuberculous cystitis, often experience great benefit from a change of residence to a warmer climate.

Vaccines I have not found of much use in uncomplicated cystitis, but where other portions of the urinary tract are also involved great benefit may often be obtained from autogenous detoxicated vaccines.

In all cases a practitioner should set his standard of cure by the physical components of the urine rather than by the amelioration of symptoms, making it his ambition to obtain a urine devoid of leucocytes, organisms, and excess of mucus, as a guarantee of freedom from future relapse, rather than being satisfied with the more easily obtained relief from frequency and urgency of micturition.

When antiseptics are being given, diuresis acts disadvantageously in diluting the antiseptic. In such circumstances the relative values of antiseptics and of diuresis must be carefully appraised. A good plan is to give a largish dose of hexamine one hour before retiring, and at the same time to limit the intake of fluids during the evening. A high concentration of hexamine during the period when the urine is longest in the bladder is thus obtained. If, however, there is nocturnal frequency the value of this manoeuvre will be lessened.

Urinary Department, Royal Hospital,
Salford, Manchester, &c.

Special Articles.

THE ESTIMATION OF SUGAR IN BLOOD.

BY G. ROCHE LYNCH, M.B., B.S., D.P.H. LOND.,
PATHOLOGICAL CHEMIST, ST. MARY'S HOSPITAL; JUNIOR
OFFICIAL ANALYST TO THE HOME OFFICE.

THE new knowledge which has of recent years been achieved in connexion with diabetes mellitus and the various allied conditions of abnormal metabolism of sugar has changed to a great extent our aspect of these conditions. The advances which have been brought about lie mainly in four directions: (1) diagnosis, (2) dietetic treatment, (3) insulin treatment, and (4) prognosis. The success which has crowned the efforts of various workers has been obtained not only through the enormous amount of experimental work performed chiefly in this country and in America, but through a considerable improvement in the technique of laboratory methods, whereby accurate and simplified analytical procedures have been evolved. Without these improvements progress would have been poor compared to what has been achieved. The outstanding biochemical advance which has accrued is that accurate estimations may now be made of the amount of reducing sugar in the blood; for this purpose only a few drops of blood, easily obtained by pricking the finger or ear, are needed. It is not so very long ago that an investigation of the sugar in blood required about an ounce of blood from a vein, whereas now equally reliable methods are in daily use for which two drops of blood suffice. These methods have not only made possible frequent estimations of blood-sugar in patients, but permit the biochemist to study the fate of the glucose for long periods of time after the administration of carbohydrates by the mouth, without appreciable discomfort to the patient. Of other advances the methods of estimation of the degree of acidæmia and ketosis may be mentioned, whereby the relative seriousness of severe cases of diabetes mellitus may be gauged.

The Problem as It Affects the Practitioner.

Those who have followed the recent work on this fascinating subject, and who have the responsibility of treating cases of diabetes mellitus, or of other abnormalities in the metabolism of sugar, must have realised that if they are to make accurate diagnosis and apply intelligent treatment to their patients, they must be in a position to control their efforts by estimations of blood-sugar percentage, either with or without a preliminary known dose of carbohydrate. To the specialist in these diseases, and to the biochemist, such an estimation presents no great difficulties, nor, it may be added, to the student of medicine working in admirably equipped laboratories, with efficient teachers at hand to direct his energies. But to the practitioner with limited or inadequate laboratory equipment the problem is a very serious one. A simple and easy method appropriate for his use and requiring no expensive apparatus is urgently needed. It may be frankly stated for various reasons which will be detailed below that there is no suitable method available to-day. At the present time these investigations are available for the wealthy and the poor, whilst but little provision has yet been made for middle-class patients. These may be willing and able to pay ordinary medical fees, but quite unable to afford the extra expense involved by special investigations, or special treatment which may have to be carried on during the rest of their life. This question is exercising the minds of practitioners and the public, and no solution has yet been found.

The Principles Involved in Estimation of Blood-Sugar.

For the benefit of those practitioners who have access to laboratory accommodation and possess some biochemical experience the various methods of

carrying out this estimation may be discussed from the point of view of accuracy, convenience, and cost of outlay. The operation is one of delicacy, for it must be remembered that the amount of blood usually taken for the estimation is not more than 0.2 c.cm., and the glucose in this volume of blood amounts to only 0.2 mg., or about 1/320th of a grain.

The first stage of the estimation is accurately to weigh or measure the blood taken for the estimation. If it is decided to weigh the blood, as recommended by some observers, it will be necessary to purchase a torsion balance which is designed to weigh only very small amounts up to about 0.5 g., but to weigh these accurately. The cost of such a delicate instrument, which the practitioner would scarcely need for any purpose other than this, would be from £10 10s. to £12 12s. Alternately the blood may be measured in a special pipette graduated to contain some fraction of a cubic centimetre, usually 0.2 c.cm., which is a convenient amount to obtain from a single finger prick. As these pipettes hold 0.2 c.cm., but do not give out 0.2 c.cm., it is necessary to wash them out carefully with the liquid that the blood is being placed in. There should be no difficulty in using these pipettes after a certain amount of practice, and they cost only a few shillings each.

Removal of Protein.—The next stage is the removal of the protein, which is precipitated generally by one of two methods, the tungstic acid process of Folin and Wu, or the sodium sulphate and dialysed iron method of Maclean. Other methods are recommended by certain observers, but one of the two just mentioned will be found generally applicable. In practice it is first necessary to dilute the blood with distilled water in order to dilute the blood, and to produce a convenient volume of liquid which will filter readily. The volume of the liquid prior to filtration must be ascertained, so that a known aliquot part of the liquid, and consequently an aliquot part of the original blood, may be used for the actual estimation, for during the process of filtration some of the liquid is lost. A bright colourless filtrate having been obtained, the actual estimation is made. In all, except two of the methods which it is proposed to discuss, some form of alkaline copper solution is employed, as in the familiar Fehling's or Benedict's tests, but the quantities of the various chemical substances used are necessarily much smaller. The amount of copper, however, must be kept in excess of the amount required to oxidise the whole of the sugar present in the blood filtrate. When the blood filtrate containing the glucose has been boiled with a convenient amount of the alkaline copper solution for a given time, long enough to produce as much cuprous oxide as possible, the estimation resolves itself into the determination of the amount of cuprous oxide present. Two methods are employed to determine this—(1) colorimetric and (2) titrometric.

(1) *Colorimetric Method.*—Here advantage is taken of the fact that cuprous salts give a blue colour with phosphomolybdic acid, the intensity of which colour is directly proportional to the amount of cuprous copper present. If, then, as a control, a known quantity of a standard solution of glucose is taken and boiled in a second tube for the same time as the unknown blood filtrate, both tubes being subsequently treated in precisely the same way, the colours produced may be compared, and from this comparison an estimate of the quantity of sugar in the unknown may be formed. A reliable colorimeter, such as the Dubosq or the Kober instruments, is essential, and such an instrument costs about £25.

(2) *Titrometric Method.*—Here the cuprous oxide formed by the reducing action of the glucose is converted back to the cupric oxide by adding a known amount of the oxidising agent (which must be in excess) to the blood filtrate (A) containing the unknown amount of glucose and thence some of the copper in the cuprous state; the same amount of oxidising agent is added to a control solution (B). The titration

consists in determining the amount of the oxidising agent still present in (A) which contained the unknown amount of the cuprous compound, and in (B) the liquid which contained no cuprous compound—i.e., a blank estimation. The difference in the readings of the burette corresponds to the amount of the cuprous copper present in (A). The exact quantity of glucose which would have been necessary to effect the original reduction from cupric to cuprous oxide is found by reference to prepared tables.

Method without the Use of Copper.—When copper is not used a different method of protein precipitation is employed. Here excess of picric acid is added to the blood, which has been laked by dilution with a known volume of water; the proteins are precipitated and filtered off. The solution is then made alkaline with sodium carbonate and an alkaline solution of picric acid is added. A parallel experiment is made with a known solution of glucose. The liquids are boiled for a given time and compared in a colorimeter, the colours produced being reddish-brown.

A Survey of Various Methods.

It may be of interest to discuss in more detail each method as described by its author and to enumerate the advantages and disadvantages from the point of view of the worker who has not at his command elaborate laboratories and equipment. In practice, owing to the delicacy of these operations, scrupulous care must be taken to follow in the smallest detail the technique laid down by the various authors; unless this care is maintained in each successive experiment results will be obtained which are not strictly comparable, and a series of blood-sugar curves obtained over a period of time will have no value. All standard solutions must be accurately made up or obtained from firms whose reputation for the preparation of such solutions is beyond reproach. Many of these solutions do not keep, and consequently fresh supplies must be obtained at frequent intervals. In biochemical manipulations of this type the workers who get the best results are those who are constantly performing these operations, and even then errors, often unaccountable, will creep in. Thus control experiments must be frequently performed and standard solutions must frequently be tested. A measure of facility in the use of the various varieties of pipettes and the graduated glassware is assumed.

In the following survey of the methods in use no attempt is made to describe the method in detail; the worker who decides to adopt a particular method is strongly recommended to read carefully the original paper of its author; a list of references for this purpose will be found at the end of this article.

*Bang Method.*¹—The first valuable microchemical method to appear was Bang's; this paved the way for other methods, but for various reasons which need not be discussed here it cannot be recommended, and is probably not extensively used to-day. The method requires the torsion balance.

*Folin and Wu Method.*²—These authors introduced the tungstic acid protein precipitant which forms an essential part of many methods. They worked with a considerable quantity of blood, but were also concerned with the estimation of a number of other substances in the same specimen of blood. They used the phosphomolybdic acid reagent of Folin and Denis for the sugar estimation, and in a later paper they improved on this reagent. The actual amount of the blood filtrate which they require for the estimation corresponds to 0.2 c.cm. of blood. Probably the tungstic acid method for the removal of protein is the best at our disposal, for only the minutest traces, if any, of the blood proteins appear in the filtrate.

*Mackenzie Wallis and Gallagher's Modification.*³—Mackenzie Wallis and Gallagher using this method employ the torsion balance to weigh the blood which is collected by soaking it into a piece of filter-paper weighed before and after impregnation. The

paper is then soaked in water for 45 minutes and the liquid treated with the tungstic acid protein precipitant and estimated by the phosphomolybdic acid reagent. This method requires both torsion balance and colorimeter and the 45 minutes delay is a nuisance when blood-sugar curves are being made at half-hour intervals.

*Calvert's Modification*⁴ consists in collecting the blood in a platinum capsule of known weight and weighing with the torsion balance. Protein precipitant methods and the phosphomolybdic reagent are the same in this method, but instead of comparing the colour against a glucose standard, Calvert used a piece of blue glass which has been carefully matched against the blue derived from a known amount of glucose. He thus avoids the preparation of a glucose standard colour for each estimation; this is an advantage since standard solutions of glucose do not keep well and frequent preparation of these solutions is required. A criticism of the method may be offered—that it is almost impossible in practice exactly to match a blue liquid with a piece of blue glass, and that comparison of the relative depth of two colours when they are not exactly of the same tint is often very difficult. When the platinum capsule is dropped into the distilled water the blood diffuses out very quickly; so that the method has the advantage that the precipitation of the protein may be proceeded with almost at once.

*Picric Acid Method of Lewis and Benedict.*⁵—This method need hardly be seriously considered here as 2.0 c.cm. of blood are required for the estimation. Its application is thus very limited compared with the scope of those methods requiring only 0.2 c.cm. The method is, moreover, rendered inaccurate if there is excess of creatinine in the blood, which circumstance may occur in azotemic nephritis.

*Maclean's Method.*⁶—Maclean, in 1914, brought out a method using 1 c.cm. of blood, and in 1920 modified it so that 0.2 c.cm. of blood would suffice. This modification, like the original, is a titrimetric method. The blood is measured in a pipette and run into the sodium sulphate solution (made faintly acid with acetic acid); the liquid is boiled, treated with dialysed iron, and filtered, an aliquot part of the filtrate being taken for the estimation. The liquid is boiled with the alkaline copper solution which also contains the oxidising agent iodic acid; as long as the solution is alkaline the iodic acid is present as the inert potassium salt. As soon as hydrochloric acid is added the iodic acid is liberated and reconverts the reduced copper into the cupric state. The excess of the iodic acid reacts with hydriodic acid, also formed from potassium iodide by the hydrochloric acid, and free iodine is liberated. This iodine is titrated by means of standard thiosulphate solution, starch being used as indicator, and the difference in the readings in the burette between a blank and the blood filtrate estimations give on reference to a specially prepared table the percentage of sugar in the blood. In this method neither torsion balance nor colorimeter is required, but extreme care to ensure the accuracy of the standard solutions is necessary. The thiosulphate solution used is 1/400 normal in strength and since it does not keep has to be prepared daily by dilution from 1/10 normal solution. The latter requires renewing about every two months. Certain technical difficulties in connexion with the heating of the blood filtrate and the copper solution may arise; a special gas pressure manometer is recommended to ensure a constant rate of heating. The outlay for apparatus is small when compared with many other methods, and the fact that analysts on general principles prefer titrimetric to colorimetric methods is a point in its favour.

*Cole's Modification*⁷ closely resembles Maclean's method, but the protein precipitant used is different. It appears to have no advantages over the Maclean method, and the dilute thiosulphate solution for the final titration is stronger than the one which Maclean uses, rendering the differences corresponding to the

amounts of glucose much smaller than in the Maclean method: thus it gives a smaller margin for error.

Hagedorn and Jensen's Method.^{8,9}—Hagedorn and Jensen have described a method in which zinc hydroxide is used for precipitating the proteins; the sugar is then estimated by means of potassium ferricyanide instead of copper, the final titration being achieved by iodine and thiosulphate. 0.1 c.cm. is required for the estimation. The method appears to be sound, but I have had no personal experience of it.

Conclusion.

It will be seen that there is much similarity between the various methods of estimating sugar in blood—the differences being mainly in technical detail. It rests with the individual to decide for himself which method he finds most convenient. I personally prefer the Maclean method and have found it entirely satisfactory. I believe that if sufficient care is paid to detail the practitioner with some experience of biochemical work, who has decided to undertake these estimations himself, will be able to master the technique. It must also be borne in mind that from financial considerations this method invites serious consideration. The descriptions in the original papers of the authors have been followed closely, but there is no objection to certain modifications such as measuring the blood instead of weighing it prior to adopting one of the colorimetric methods; for this purpose it will be sufficiently accurate to assume that 1 c.cm. of blood weighs 1 g. The treatment of diabetes mellitus by insulin is a matter for serious consideration in the immediate future. Whether it will become a practical proposition to give certain patients daily hypodermic injections for the rest of their lives is a problem, but one thing is certain in the light of our present knowledge, that not only will diagnosis, but also treatment, whether by insulin or other means, require control by blood-sugar estimations from time to time. To the wealthy this necessity will present no difficulties, but to the poorer members of the community expense must be a factor. If the lives of diabetics can be prolonged it seems possible that some State assistance of a financial nature will be required. It would seem rational that if sufferers from avoidable disease can receive free treatment, the unfortunate sufferers from the unavoidable disease under discussion might equally well expect State assistance.

THE Council (President, Her Grace the Duchess of Portland) and committees of the Ivory Cross announce the private view of the Ivory Cross dental film at Australia House, Strand, W.C. 2, on Tuesday, June 12th, at 5 P.M.

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held on June 23rd, in the Guildhall, Cambridge, when a discussion on the Grading of Milk will be opened by Mr. J. E. Purvis, M.A., Secretary to the State Medicine Syndicate, followed by Dr. J. H. C. Dalton, Dr. F. Robinson, Councillor Alder, and Dr. Andrew J. Laird. The chair will be taken at 10.30 A.M. by Prof. H. R. Kenwood. In the afternoon visits will be paid to the Field Laboratories, Milton-road, where Dr. Stanley Griffith will give a demonstration in connexion with research on Tuberculosis, and to the Stetchworth Dairies, certified milk farm, Old Chesterton, where a party will be conducted by Mr. Ronald Kay. Those proposing to attend the meeting should notify the hon. local secretary, Dr. A. J. Laird, Guildhall, Cambridge, not later than June 16th.

THE CONSTANTINOPLE BOARD OF HEALTH.

BY F. G. CLEMOW, C.M.G., M.D.,

FORMER BRITISH DELEGATE TO THE BOARD AND PHYSICIAN TO H.M. EMBASSY, CONSTANTINOPLE.

PART III.*—THE SANITARY SERVICES.

The Red Sea Sanitary Service, the Mecca Pilgrimage, and the Hedjaz Railway.

In the Red Sea service there were but two lazarets—those of Camaran and of Abou-Saad, near Jeddah. Both have been fully described by the author in papers previously published in *THE LANCET*,¹ and need therefore only be briefly alluded to. The lazaret of Camaran, built on the island of that name near the south end of the Red Sea, was a large and in many respects an excellent institution, with good disinfecting pavilions, distilling apparatus, ice-machine and accommodation for 5000 to 6000 pilgrims. Under the Conventions all ships from beyond Bab-el-Mandeb are required to proceed to this lazaret and undergo certain measures. The lazaret of Abou Saad-Wasta-Abou Ali was a small and very imperfect establishment, built on three islands bearing those names, a few miles from the port of Jeddah. It was permitted to receive pilgrim ships conveying a number of pilgrims less than 5 per cent. of the ship's net tonnage, although, as just stated, the Conventions required all pilgrim ships from the south to go to Camaran. It also dealt with ships coming from the north. It was, however, badly provided with houses for the pilgrims; indeed, there was accommodation for some 800 only, but with tents this number might be doubled. The need of a large lazaret for pilgrim ships coming from the north had long been felt. The difficulty was to find a spot where such lazaret could be put up. Yanbo and El Wedj have both been suggested; both are exceedingly small ports, quite unsuited for the purpose, and there are no other ports on the Hedjaz coasts north of Jeddah. There were three Turkish sanitary offices in this service under a medical officer—Jeddah, Yanbo, and Hodeidah—and six with only a non-medical personnel. All, it need scarcely be added, have ceased to be on Turkish soil. The lazaret of Camaran is now administered by the British, and that of Abou-Saad by the Hedjaz authorities.

The Mecca pilgrimage and its sanitary control are questions too large and complex to be discussed at length here. The Constantinople Board had medical officers stationed at Jeddah, Mecca, and Medina; the two latter were always Moslems. They kept the Board informed on all points of sanitary interest connected with the pilgrimage. The Mecca medical officer supervised the sanitary service in that town and co-operated with other Turkish officials in carrying out measures to meet the risk arising from the overcrowding of pilgrims, or the outbreak of disease among them, and to deal with the highly insanitary conditions connected with the ceremonial sacrifice of thousands of animals, which takes place in the valley of Muna at the height of the pilgrimage. The measures taken in this latter connexion were reported to be fairly satisfactory, and were largely aided by the great heat and dryness of those regions. But there can be no question that, generally speaking, the sanitary supervision of the pilgrims after their arrival in the Hedjaz has always been inadequate,² and it

* Parts I. and II. were published in *THE LANCET* of May 26th (p. 1074) and June 2nd (p. 1126), respectively.

¹ *THE LANCET*, 1907, i., 1188, 1251, 1317, 1389, 1518, 1607, 1741, 1810; ii., 51, 114, 190, 324.

² This inadequacy had long been recognised and had been the subject of countless reports, of protests from foreign governments, of "vœux" of International Conferences, and of sporadic efforts at improvement. Finally, in 1910, the Turkish Government set up a Hedjaz Sanitary Council, a purely Turkish body, charged with the reorganisation of the interior sanitary measures in the Hedjaz, and authorised, with the consent of the Powers, to levy a special tax of 10 piastres a head on the pilgrims. It had already done something towards improving the conditions before the cataclysm of 1914.

will continue to be so until an efficient sanitary service is established there, run on modern and scientific lines. One main difficulty in the past has arisen from the fact that only Moslem officials may work there, and any intervention by the Western Powers was resented and indeed impossible. This difficulty is likely to be as great under the present political status of the Hedjaz as when it was a Turkish province; and the only hope for the future is that the Moslem world will be able to substantiate its claim to produce administrators, including medical and public health officials, as capable as those of other countries; or, failing this, that it will consent to accept the aid, or at least the advice (with some guarantee that that advice will be acted on), of European experts.

While public health supervision in the Hedjaz itself is a most important element in the problem of the effective sanitary control of the pilgrimage, it is not the only one; the problem covers all Moslem countries, and should include the preservation of the health of the pilgrims from the moment they leave their homes to the moment they return to them. The suggestion, therefore, recently made to the Health Committee of the League of Nations—that some form of Coördinating Commission, of an international character, should be set up, charged with the coördination of the measures taken by the health authorities of the various countries concerned in connexion with the Hedjaz and other pilgrimages—is to be commended in every way, and if properly carried out should lead to invaluable results.

The Hedjaz Railway was opened to Medina in the autumn of 1908. In June of that year the Constantinople Board sent a special commission down the line, with the object of selecting a site for a lazaret, where disinfection and other measures could be applied to the pilgrims travelling by the line. An excellent site was chosen at Tebuk,³ some 450 miles south of Damascus, and the beginnings of a large and effective lazaret had been made there before the war put an end to all such schemes. The opening of the line greatly increased the danger of the spread of disease by the returning (and even by the descending) pilgrims, and its sanitary protection will always be an important part of the main problem. The line passes through territory that is now partly under the authorities of the kingdom of the Hedjaz, partly under British, and partly under French mandatory authorities. Here again there will always be great need of effective coördination in the application of sanitary measures.

The Turco-Persian Frontier Sanitary Service and the Shiah Pilgrimage.

The sanitary organisation on this frontier and in connexion with the movement of pilgrims and carriage of dead bodies to the Shiah holy places has already been fully described in THE LANCET,⁴ and may be very briefly summarised here. There was a small and quite inefficient lazaret at Basra, and a better, but still imperfect, one at Khanikin, on the main route from Bagdad to Kermanshah in Persia. As an exception to the general rule that the Constantinople Board did not deal with interior sanitary measures, the Board had also medical officers at Bagdad, Nejef (the principal "holy city"), and at Erzeroum, Bayazid, and Van, near the northern part of the frontier. In addition there were sanitary offices, with clerks, foot-guards, and mounted guards, to check "sanitary contraband" (particularly in the matter of dead bodies) at 17 other places in those regions. The Board sent also a delegate to the Sanitary Board in Tehran, and had another "delegate" permanently stationed at Kermanshah, in Persia, as a "poste d'observation."

THE FINANCIAL ARRANGEMENTS OF THE BOARD.

It only remains to speak briefly of the Board's financial arrangements. At the time of the Constantinople International Sanitary Conference of 1866, it was realised that the tariff, as fixed in 1840, did not provide a sufficient income to cover the expenditure; and, as the Ottoman Government had to make up the difference, an effort was made to introduce a new and higher tariff. As the Board itself did not possess the power to do this, another international body had to be created, expressly charged with the study of this question and the preparation, if necessary, of an increased tariff. This body, known as the Mixed Commission for Revision of the Ottoman Sanitary Tariff, first met in 1869 and published its report in 1871. The report, signed by the Porte and all the Powers interested, was mainly concerned with proposals for the increase of sanitary dues and with the general financial arrangements of the Board and the administration it directed. Thus it laid down that the cost of construction, hire, and upkeep of lazarets, quarantine stations, and health offices, as also certain other expenses, were to be borne by the Turkish Government, while the pay of the employees and all other outlay was to be covered by the Board's funds. The latter were derived from taxes on shipping, quarantine dues on pilgrims and passengers, and a charge on all dead bodies brought for burial in the Shiah holy places of Mesopotamia.

This is but a very brief outline of a somewhat complex financial arrangement. It was a good working scheme, if it had been kept to by both sides, but unfortunately it was not. When the first Mixed Commission dissolved in 1871, it was agreed that that body should in future meet every three years to revise the Sanitary Tariff in accordance with the varying needs of the time. This agreement, however, was not adhered to. It met again in 1875-76; in 1881-82; and in 1888-96. Each successive Commission laid down in increasing detail the functions and powers of the Board, prescribed the number and composition of its various committees, fixed the nature and pay of every post in the sanitary service, and so forth. The report of the fourth Commission was, however, rejected by Turkey and some other Powers, and consequently that of 1882 remained in force until a fresh Mixed Commission was convoked at the end of 1904. This fifth Mixed Commission held its first meeting in January, 1905. It very soon became clear that the delegates composing it (who were for the most part, but not entirely, the delegates sitting on the Board itself) had no first-hand knowledge of the large and important sanitary establishments they were called upon to administer. At the end of 1905, therefore, a Commission of Inspection, composed of three members of the Board, was sent to inspect and report upon the lazarets of the Red Sea and Syrian coasts, and to indicate the reforms needed and their probable cost. Subsequent Commissions of Inspection visited each and all of the sanitary establishments named above, and produced a series of detailed reports, illustrated by maps, plans, and photographs, and accompanied by estimates, prepared by architects or engineers attached to the various missions, of the cost of the repairs proposed. It was my privilege to be a member and the "rapporteur" of each of these Commissions, with one exception (that to the northern part of the Turco-Persian frontier).

By the end of 1910 the larger number of the missions of inspection had completed their tasks and presented their reports, and the Mixed Commission was thus in a position to estimate the cost of the greatly needed reforms. The situation was then, and had been for a long time, a peculiarly anomalous one. The Constantinople Board possessed a large invested reserve fund (derived mainly from the fact that the sanitary tariff had been fixed at too high a figure), yet it was unable to employ this for the repair of the lazarets, since, as stated above, such repairs were,

³ The question of the choice of Tebuk and the whole problem of the sanitary protection of the line were discussed at length in papers published by the author in the *Revue d'Hygiène et de Police Sanitaire*, March and April, 1910.

⁴ THE LANCET, August 12th, 19th, and Sept. 2nd, 1916.

under binding conventions, at the charge of the Turkish Government. As a result, however, of the continual evasion by the latter of its obligations in this matter, and in spite of large advances made by the Board to that Government to cover the cost of the most urgent repairs, many of the lazarets had fallen into a state of most serious disrepair. Early in 1911 it fell to me, as British delegate, to make a series of proposals for putting an end to this anomalous state of affairs; and on May 20th of that year, an Interim Report of the Mixed Commission, embodying those proposals with but slight modifications, was signed by all the members of the Commission, Turkish and foreign. Briefly, the decisions thus taken may be summarised as follows: Without modifying the conventions then in force, and as a wholly exceptional measure to meet a wholly exceptional situation, a sum of £T.280,000—over a quarter of a million sterling—was voted from the Board's funds, to be spent in putting in order all the Turkish lazarets and disinfecting stations and in creating new ones. At the same time the sanitary dues on shipping were reduced by 20 per cent.; the pay of the employees was largely increased; and some other minor reforms were introduced. In the course of 1911-12 the Interim Report was ratified by the Porte and the Powers, and several of the decisions had already been applied, when the outbreak of the Turco-Balkan war of 1912-13 inevitably suspended the execution of the others, and all hope of their being carried out disappeared when the world cataclysm of 1914 supervened.

The Board since 1914.

Of the latest phases of the Constantinople Board of Health and of the manner in which the sanitary administration entrusted to it was conducted during the war and since the Armistice, it will be impossible to speak at any length here, since to do so would be to touch upon many questions of very recent political history and matters which are outside the scope of this survey. It may, however, be stated that in October, 1914, a few weeks before Turkey came into the war, the Ottoman Government declared the Capitulations at an end, and this was immediately followed by an intimation that the presence of foreign delegates on the Board of Health, dependent ■ it was on those Capitulations, was no longer necessary. Neither of these arbitrary and unilateral declarations was accepted by the Powers. After the entry of Turkey into the world war, the Turkish Government took over the sanitary administration and continued to maintain it as a Turkish institution. But navigation in Turkish waters had practically come to an end; the pilgrimages, Sunni and Shiah, had all but ceased or had passed out of Turkish jurisdiction; and it was only by hand-to-mouth expedients that anything in the nature of a system of sanitary defences was maintained at all. Fortunately the Board's reserve funds were mostly deposited in banks outside Turkey, and therefore remained intact. On the occupation of Constantinople by the Allies after the Armistice, the matters formerly dealt with by the Board were taken over by various Inter-Allied sanitary commissions.

SANITARY ORGANISATION IN THE FUTURE.

The future of the sanitary organisation in Turkey must be passed over even more briefly. The only portions of the maritime sanitary defences in what remains of the Turkish Empire that are of primary interest to Western Europe are those in the Straits; but they are of vital interest from the sanitary point of view. Whatever may be the political and territorial changes brought about in those regions when peace again reigns there, the Straits that join the Black Sea with the Mediterranean must always offer great risk for the importation of disease to Turkey and to other European countries. The danger is not only great but is an increasing one. For, on the one hand, when peace is restored, a great extension of the network of railways in the Caucasus, Asia Minor, Central Asia, Siberia, Mesopotamia, and Persia may confidently be anticipated. And, on the other hand,

the number of pilgrims to the Hedjaz has enormously decreased during the last nine years, and this can only mean that there is taking place in those countries a great accumulation of Moslems who are only awaiting peace to accomplish their Haj. The result will be that, when free movement is re-established, there will be a vast outflow of passengers and pilgrims coming from Black Sea ports and passing through the Bosphorus and Dardanelles to their various destinations; and Europe may well demand that a strong system of sanitary defences be established and maintained to her satisfaction in that important waterway. These considerations have already engaged the attention of the Health Committee of the League of Nations and of the International Health Office in Paris, and they were prominently brought forward in the recent negotiations at Lausanne.

THE NEW AND PROJECTED BUILDINGS AT UNIVERSITY COLLEGE, LONDON: VISIT OF THE KING AND QUEEN.

ON May 31st the King and Queen visited University College for the purposes of laying the foundation-stones of the new obstetric hospital and the new nurses' home of University College Hospital and of opening the new anatomy building of University College, which was described in the columns of THE LANCET last week.

Address and Presentations.

In his address to the King, Sir Ernest Hatch, chairman of the General Committee, explained that by Mr. John D. Rockefeller's munificent gifts of £835,000 to the Medical School and £370,000 to University College, the governing body was placed in a position to proceed with a scheme for the erection of new buildings for anatomy and the allied sciences of histology and embryology, and for the extension of facilities for teaching physiology and pharmacology. Further, the hospital and the medical school were enabled to provide 120 additional beds for the purposes of the medical and surgical units, and 60 beds for a new obstetric unit, with adequate provision for laboratories, including a special laboratory for biochemistry, and to build and equip a new nurses' home to provide accommodation incidental to these changes.

The following ladies and gentlemen were then presented to their Majesties by Sir Ernest Hatch: Lord Oranmore and Browne, vice-chairman of the General Committee; Major H. A. Wernher, chairman of House and Finance Committee; Sir Herbert Samuelson, member of the General Committee; Sir John Rose Bradford, senior physician; Mr. Raymond Johnson, senior surgeon; Dr. G. F. Blacker, Dean of the Medical School; Dr. A. M. H. Gray, Vice-Dean of the Medical School; Dr. Herbert Spencer, senior obstetric physician; Prof. T. R. Elliott, director of Medical Unit; Mr. C. C. Choyce, director of Surgical Unit; Mr. Paul Waterhouse, architect of the new nurses' home; Mr. George Hornblower, architect of the new obstetric hospital; Mr. Arthur H. Barker, consulting engineer for new buildings; Mr. J. Gerald T. Buckle, secretary to the corporation of the hospital; Miss D. Finch, R.R.C., late matron; Miss R. E. Darbyshire, matron; Dr. L. H. W. Williams, President of University College Hospital Medical Society; and Mr. Walter Lawrence, contractor for the building. The following were also presented by the Vice-Chancellor of the University of London: Sir E. Cooper Perry, Principal; Sir Gregory Foster, Provost; Mr. A. T. Taylor, chairman of the Building Committee; and Prof. Elliot Smith, Dean of the Faculty of Medical Sciences.

The King's Reply.

The King, in reply to the address, said there could be but few instances on record in which any foundation had received, like this College and Medical School, £1,200,000 from a single benefactor in a single gift. And the magnificent generosity of the Rockefeller Trustees was the more impressive since it had been bestowed by a citizen of the United States of America.

upon a college and hospital in London, and thus upon the people of Great Britain and the Empire. It has been said, he continued, that science knew no frontiers, and, indeed, the declared purpose of the Trustees was "to promote the well-being of mankind throughout the world." That they should have selected the University of London to receive this princely endowment was not merely a high and well-deserved compliment and the creation of yet another tie of sympathy and friendship which linked us with the United States, but it was also the evidence and declaration of their conviction that the progress of science and the welfare of mankind were not delimited by national or racial boundaries, and that work done

first was the maternity hospital and the obstetric unit, of which it forms a part. The Queen had always been actively interested in the care of maternity and infant life and keenly conscious of its fundamental importance to the national health. It was unfortunately true that the present position was not wholly satisfactory, and that every year many lives were lost in childbirth and many women suffered injuries to health which might be prevented if better facilities for treatment were available. Two of the chief requisites for bringing about a better state of things were to ensure that medical men were well and efficiently trained for their work, and to provide maternity hospitals in which patients may be received. The Queen was also

Facade of the New Anatomy Building at University College, London.

here in London for the relief of human suffering, the improvement of medical education, and the advance of science was a service to the whole world.

It was not, however, only the magnitude of the endowment which lent importance to the occasion. These buildings were designed for new and far-reaching developments in the traditional organisation of British medical education. The Rockefeller Trustees were chiefly influenced in their gift by the establishment at the College of what was known as the "unit system" of medical teaching, the essence of which had been explained in the memorandum¹ on Medical Education in England, recently published by the Ministry of Health. This was a substantial development of the traditional British system, which entrusts the clinical teaching of medicine to men of distinction who are actively engaged as private practitioners. No appreciation could be too great for the devotion with which eminent physicians and surgeons had given, and were giving, their services to the treatment of hospital patients and the training of students. But the advance of knowledge and the ever rising standard of medical education had necessitated reorganisation, which would give impetus to the more effective training and equipment of the British practitioner, with corresponding benefits to the health, well-being, and happiness of the people. The underlying principle was as old as Ecclesiasticus: "The wisdom of a learned man cometh by opportunity of leisure; and he that hath little business shall become wise." Its specific application to medical teaching and research was new, in this country, at all events.

There were two features in the scheme of which the Queen had learned with particular satisfaction. The

gratified that the claims of the nursing service had not been overlooked.

Laying of the Foundation-stones.

After the foundation-stones had been laid, that of the obstetric hospital by the King and that of the nurses' home by the Queen, the King opened the doors of the new anatomy buildings by pressing an electric button, and their Majesties visited the lecture theatre, the library, and the dissection rooms, and were particularly interested in the anatomical transparencies which are intended to facilitate the study of anatomy by comparison of those transparencies with X ray appearances. An X ray photograph of the mummy of Tothmes IV., taken several years ago for the purpose of determining his age, also greatly interested both the King and the Queen, and His Majesty evinced his acquaintance with anatomical learning by explaining to the Queen the significance of certain X ray appearances in connexion with epiphyseal development.

In the museum the following presentations to their Majesties were made by Viscount Chelmsford, chairman of the College Committee: Mr. Felix V. Schuster, a treasurer of the College; Prof. F. M. Simpson, the architect; Sir James Carmichael, the contractor; Prof. J. P. Hill, the Vice-Dean of the Faculty of Medical Sciences; Prof. E. H. Starling, the Jodrell Professor of Physiology; Prof. D. M. S. Watson, Jodrell Professor of Zoology and Comparative Anatomy and Dean of the Faculty of Science; Miss Winifred Smith, the tutor to women students; Dr. Walter Seton, the secretary of the College; Dr. H. Woollard, the Sub-Dean of the Faculty of Medical Sciences; Mr. J. Harris, the President of the Union Society; and Miss Joan Lush, the President of the Women's Union Society.

¹ See THE LANCET, May 5th, p. 909.

PREVENTION OF VENEREAL DISEASE IN THE CIVIL COMMUNITY. REPORT OF THE COMMITTEE OF INQUIRY.

THE Committee of Inquiry on Venereal Disease has now reported to the Minister of Health. This Committee was constituted pursuant to correspondence which passed between Sir Alfred Mond, then Minister of Health, and Lord Dawson in the early part of last year. Sir Alfred Mond then wrote:—

"I have noted with interest your proposal that a committee of medical men possessing the requisite special knowledge should be constituted to inquire into certain aspects of the problem of venereal disease. I understand that in your opinion the best hope of solving this complex problem is first to endeavour to secure an authoritative pronouncement on its medical and medico-administrative aspects, the more so as men of eminence hold divergent views upon it. The community as a whole would then consider this medical pronouncement side by side with the weighty moral and social issues involved, and through its responsible representatives determine the right policy to be pursued. As Minister of Health I am deeply concerned with this grave problem, and write to say that I will afford encouragement and support to the holding of the investigation."

REFERENCE AND PERSONNEL.

The reference to the Committee was in the following terms: "To consider and report upon the best medical measures for preventing venereal disease in the civil community, having regard to administrative practicability, including cost"; and its membership consisted of:—

Lord Trevethin (Chairman); Mr. T. J. C. Tomlin, K.C. (Vice-Chairman); Mr. C. J. Bond, F.R.C.S.; Surgeon-Captain Reginald Bond, R.N.; Dr. John Brownlee; Prof. W. Bulloch, F.R.S.; Dr. D. S. Davies; Prof. G. Dreyer, F.R.S.; Group-Captain Martin W. Flack, M.B.; Lieut.-Colonel F. E. Fremantle, M.P.; Dr. Dorothy Hare; Prof. H. R. Kenwood, M.B.; Major-General Sir W. B. Leishman, M.D.; Dr. F. N. K. Menzies; Sir Frederick Mott, F.R.S.; Dr. Morna Rawlins; Dr. J. H. Sequeira; Sir Bernard Spilsbury, M.B.; Mr. Kenneth Walker, F.R.C.S. (Prof. Bulloch found himself unable to attend the meetings of the Committee and resigned his membership at an early stage.)

PROCEDURE.

The Committee held 28 meetings (not including seven meetings of subcommittees) and examined orally a large number of witnesses in the order as follows:—

Brevet-Colonel L. W. Harrison (Ministry of Health); Sir Archdall Reid, M.D.; Dr. E. W. Hope (M.O.H., Liverpool); Dr. W. A. Young (Asst. M.O.H., Manchester); Dr. Margaret Rorke (M.O. in charge V.D. Clinics, Royal Free Hospital and Blackfriars Skin Hospital); Dr. Charles Franks (V.D. Officer, Durham County Council); Dr. David Lees (M.O. in charge V.D. Clinic, Royal Infirmary, Edinburgh); Mr. H. Wansey Bayly, M.R.C.S., and Lieut.-Colonel E. T. Burke, M.B. (representing the Society for the Prevention of Venereal Disease); Dr. A. Mearns Fraser (M.O.H., Portsmouth); Dr. John Robertson (M.O.H., Birmingham); Sir Malcolm Morris and Dr. Otto May (representing the National Council for Combating Venereal Diseases); Lieut.-Colonel P. H. Henderson (Asst. Director of Hygiene, Eastern Command); Major A. T. Frost (O.C., Military Hospital, Rochester-row); Dr. H. Hyslop Thomson (C.M.O., Herts); Dr. C. E. Jenkins (Pathologist, Salford Royal Hospital); Surgeon-Captain P. H. Boyden, R.N.; Dr. R. A. Lyster (C.M.O., Hants); Mrs. F. A. Hornibrook (Miss Ettie Rout); Lady Barrett, Dr. Eric Evans and Dr. Louisa Martindale (representing the Medical Women's Federation); Dr. J. Middleton Martin (C.M.O., Gloster); Dr. Douglas White (representing the Association for Moral and Social Hygiene); Mr. H. W. S. Francis (Ministry of Health); Sir Leslie Mackenzie and Dr. T. F. Dewar (Scottish Board of Health); Dr. J. McGregor Robertson (Consulting Physician, Stobhill Infirmary, Glasgow); Dr. F. J. H. Coutts, Dr. E. P. Manby, and Dr. H. Meredith Richards (Ministry of Health); Mr. E. B. Turner, F.R.C.S., Sir Jenner Verrall and Dr. R. A. Bolam (representing the British Medical Association); Dr. F. C. Shrubbsall (Principal A.M.O., London County Council); Mrs. R. P. Wethered and Mr. S. Cohen (representing the Associated Societies for the Care and Maintenance of Infants); Dr. R. D. O'Leary (Med. Supt., Bethnal Green Infirmary); Mr. Frank Kidd, F.R.C.S.; Dr. A. L. Baly (Med. Supt., Lambeth Infirmary).

In addition written statements were received from: Squadron-Leader A. Grant, M.B. (Royal Air Force); Sir James W. Barrett, M.D.; Surgeon-Commander S. F. Dudley, M.B.; Surgeon-Commander D. H. C. Given, M.D.; Dr. Lydia Henry (Asst. M.O.H., Blackburn); Surgeon-Captain L. Kilroy, M.R.C.S.; Major-General Sir W. B. Leishman, M.D.; Dr. J. W. S. McCullough (Chief Officer of Health, Provincial Board of Health, Ontario); Surgeon-Commander R. J. MacKeown, M.B.; Surgeon-Commander R. J. G. Parnell, M.R.C.S.

The Committee also referred to a large quantity of literature, both British and foreign, relating to venereal diseases.

PREAMBLE.

Under the terms of reference the functions of the Committee were confined to the consideration of medical measures. Having regard, however, to the origin and nature of venereal diseases, the Committee felt that, in relation to the civil community, medical measures alone could never operate as an absolute preventive of disease, but their success must always depend largely upon the attitude towards them of the community and the coöperation of the community in securing their largest effect. This coöperation could only be hoped for if full knowledge of the nature of the problems to be faced becomes common property. Other measures should be employed contemporaneously with medical measures if the latter are to be made a success. For example, the extension of knowledge as to the nature of venereal disease and its consequences is of the first importance. The community should, as far as possible, be made to appreciate:—

(a) That promiscuous intercourse is the main cause of the prevalence of venereal disease.

(b) That there is no absolute preventive except continence, and a single exposure may result in infection.

(c) That a large number of the sufferers from venereal disease are innocent persons, especially women and children.

(d) That syphilis is a disease of great gravity which, if not treated in its early stages, may have serious results, including affections of the circulatory system and of the nervous system, as, for example, general paralysis of the insane.

(e) That syphilis is transmissible by a mother to her children, and is a frequent cause of miscarriages, still-births, and deaths in early infancy, and, in children who survive, of mutilating deformities, deafness, blindness, mental disease, and other defects.

(f) That gonorrhoea is a more serious disease than is commonly believed, and, if not promptly treated, may have serious after-consequences.

(g) That gonorrhoea is a frequent cause of sterility and serious pelvic disease in women and a cause of blindness in children born of women suffering from gonorrhoea.

(h) That the presence of these diseases in the community is a menace to the maintenance and advancement of the physical and intellectual standard of the race.

Again, in addition to the spread of knowledge, it is necessary that measures should be pursued which will diminish those conditions of life which tend to foster promiscuous intercourse and the spread of disease.

SCOPE OF MEDICAL MEASURES.

Medical measures fall into two categories: (1) Medical measures for preventing disease in, or minimising the risk of disease to, persons exposed to infection; and (2) medical measures for rendering non-infective and curing diseased persons.

1. Measures for Prevention.

With regard to these, highly controversial questions are involved. It is established that in the laboratory under conditions approximating to those which obtain in intercourse, disinfectants will destroy both *Spirochaeta pallida* and the gonococcus, and we think that a man who after exposure is thoroughly and promptly disinfected by disinfectants of appropriate nature and strength, runs little risk of infection. The chance of failure, however, increases rapidly as the interval between exposure and the application of disinfectants lengthens, and the conclusion seems to be that in syphilis such disinfection as mentioned above within an hour would generally be successful, and that in the case of gonorrhoea it has a prospect of success after a longer interval. It seems, however, to be

agreed on all hands that it is extremely difficult for a woman to disinfect herself, and that the prospects of success from disinfection by another person, however skilful, are in the case of a woman less than in the case of a man.

The question of disinfection falls to be considered under two headings: (i.) Disinfection by the person himself (hereinafter called *self-disinfection*), and (ii.) disinfection at the hands of a trained person (hereinafter called *skilled disinfection*).

Self-Disinfection and Skilled Disinfection.—Obviously the chances in favour of success are greater in the case of skilled disinfection than in the case of self-disinfection, and we see no reason to doubt that an intelligent man, if furnished with reasonable instructions, could in favourable conditions effectively disinfect himself. The foregoing conclusions as to disinfection of the individual do not, however, carry very far in determining the question whether it is advisable for the purpose of preventing venereal disease in the civil community to introduce any system or measures for affording to the general public facilities for disinfection. From the nature of the case there is very little direct evidence to assist a conclusion. The matter is largely one of speculation, influenced in each case by the views which the exponent holds generally in regard to the tendency of human nature and on questions of a moral and social character.

Conditions of Success.—The important evidence available under this head is derived from the experiences which have been obtained from measures taken in the fighting forces of our and other countries. We have had placed before us a large body of evidence of this character relating both to self-disinfection and skilled disinfection. Where satisfactory results were recorded, a great difficulty arises in determining how far those results were due to the prophylactic methods employed, or were influenced by other factors in the case, such, for example, as regulation of hours of leave of absence, control of, or exclusion from, dangerous places, liquor control, imposition of penalties upon men becoming infected, the provision of facilities for recreation, and the moral effect in time of war of appeal for restraint on grounds of patriotism. Further, the prevalence of disease among women has probably varied widely in different areas, and it has rarely been measured.

Where, however, satisfactory results were not recorded, discipline appears to have been defective or the control slack, or the medical supervision or instruction inadequate or lacking in enthusiasm, and there is much force in the argument that in any large community a condition of control and influence affecting the life and conduct of all its members such as obtains in a military body under efficient command is essential to securing substantial results from any system of disinfection.

We think, however, that we are justified upon the evidence in coming to the following conclusion:—

That in a community where there has been efficient instruction and where there is such a condition as arises from the control and influence mentioned above substantial results may reasonably be expected to follow from prophylactic measures, but that the actual result is often less favourable than has been claimed.

Question of Public Facilities.—It must be remembered that, to a large extent, exposure to infection takes place in conditions in which prompt disinfection is either impossible or can only be carried out at great disadvantage. Further, the application of disinfection by a man to himself after exposure demands an effort and care which the circumstances do not tend to promote. It is urged by some that any system of disinfection would tend to increase the number of exposures and to raise the disease rate. We have received no evidence of facts in support of this view, and we are inclined to think that those who hold it attach too much weight to the deterrent effect of the fear of disease. But, however this may be, upon the evidence which we have heard we conclude that the success of any general public facilities for

self-disinfection is likely in the civil community to be very small. At the same time, in face of the fact that disinfection in the case of an individual user, if properly and promptly applied, will in all probability be successful, we do not think that there is any justification for putting obstacles in the way of individuals who desire to procure the necessary disinfectants. The law does not to-day prevent the sale of sheaths, which afford by mechanical means a measure of protection against venereal disease, and we think that the law should be altered so as to permit properly qualified chemists to sell ad hoc disinfectants, provided such disinfectants are sold in a form approved, and with instructions for use approved by some competent authority. We suggest that the Medical Research Council should be invited to undertake this task. We think, however, that the commercial advertisement of ad hoc disinfectants should be prohibited. From a medical point of view the instruction by medical officers of venereal disease clinics of male persons attending such clinics in the preventive use of disinfectants would afford a useful means of educating the community.

Relative Cost.—Our view is that money spent on a general system of providing facilities for self-disinfection would certainly be less profitable than money spent either on treatment of disease or on those measures of education and improvement of social conditions to which we have referred above. With regard to skilled disinfection, its chances of success must necessarily be much limited by reason of the time that will generally elapse between exposure and disinfection. The cost of any general system of skilled disinfection would be large; it is a system which is wholly inappropriate to rural districts or small towns, and we do not recommend its adoption as part of any general system.

II. Measures for Treatment of Disease.

With regard to the treatment of disease, we have reached the following conclusions:—

(i.) That, speaking generally, the general medical practitioner is not yet adequately equipped with the most advanced knowledge of venereal diseases and their treatment to enable him to deal competently with all the cases that come before him, and that an improvement in medical education in regard to venereal disease is necessary; and

(ii.) That the work of existing venereal disease clinics is of high value, and that the system is one which ought to be encouraged, extended, and improved.

Defaulting.—With regard to clinics, one of the difficulties in practice arises from the tendency of patients to cease treatment before they have completed their course. According to the statistical evidence the amount of this defaulting is serious, but a closer investigation carried out in some treatment centres shows that by no means all the patients who have discontinued attendance before completing treatment were infectious. A large number of syphilis cases attending these centres were from the commencement of the treatment past the infectious stage. Further, in gonorrhœa cases the standard of cure suggested by the Ministry of Health is very high, and to comply with it patients must be treated long after all bacteriological evidence of the presence of gonococci has disappeared. Many cases classed as having failed to complete treatment appear to have ceased attendance with negative bacteriological tests for gonococci, and it is reasonable to suppose that a fair proportion of these were not infectious. The conclusion is that from the point of view of the public health the defaulting is not so serious as the statistics make it appear. It remains, nevertheless, an important factor in the spread of venereal disease.

Notification.—The question of defaulting is a topic which necessarily leads to the consideration of the question of compulsory notification of venereal disease. Apart from any statistical value which may result from notification of disease, notification itself is of little assistance unless it is supported by a system of compulsory treatment, and, if necessary, detention. It is a fact that the stigma which venereal disease

carries renders many sufferers reluctant to submit themselves to treatment, and sufferers will surely be led into concealment by any measures which threatened publicity. The principle of the present system is, by maintaining secrecy, to encourage sufferers to come to treatment and to continue treatment; and we think that in the present state of public opinion any system of general compulsory notification of venereal disease would tend to concealment and would prove a backward step.

It has been suggested by some that in order to secure unbroken attendance of patients at clinics a modified form of notification, supported by appropriate compulsory measures, should be applied to those who have once attended the clinics in order to secure their continued attendance; but in our view such a system would be more likely at the present time to deter than encourage attendance, and it seems difficult to justify the imposition of a penalty on those who have come for treatment while leaving untouched those who make no effort to seek treatment.

There is another grave difficulty in the way of any form of notification, reinforced by measures to compel treatment, that in the present state of knowledge there is no standard of non-infectivity or cure generally accepted by the medical profession, and until this has been attained it is difficult to see how any system involving notification and compulsory measures of treatment could be applied.

Improvement and Extension.—One main objective in our view should be the improvement and extension of the present clinic system. There are many respects in which we think improvements might be made:—

The provision of more suitable accommodation, the extension of hours of sessions, including greater facilities for intermediate treatment of gonorrhoea, a more adequate provision of beds for in-patient treatment, the establishment of more hostels for women attending clinics and living under social conditions which render it difficult for them to treat themselves in their homes, and the establishment of more homes or hospital beds for the treatment of children.

Instruction and Warning.—As it is agreed that it is essential for the prevention of disease that there should be widespread knowledge among the community of the nature and consequences of these diseases, it follows that the importance of giving repeated personal instruction and warning to patients attending the clinics cannot be overstated. We think that this duty must always devolve mainly on the doctors, but that it might well be supplemented by trained social workers, who for this purpose and that of giving general advice and assistance should be attached to the staff of the clinic.

Pregnancy.—It has been shown that if syphilis is detected in the pregnant woman, treatment during pregnancy is remarkably successful in securing healthy offspring, and gonorrhoeal infection of the infant at birth may generally be prevented if the danger is known. Increased facilities for medical supervision of women during pregnancy is desirable, and may in part be obtained by an extension of the system of ante-natal clinics, and by the instruction of midwives who would refer suspicious cases to a doctor. In this connexion we would also call attention to the importance of including instruction on venereal diseases in the general training of midwives and nurses.

Finance.—All improvements must no doubt be limited by the funds available, but it would facilitate the provision of more adequate accommodation if a system of capital grants such as have been made in connexion with the treatment of tuberculosis were available in proper cases. We are not in a position to make recommendations more specific than the above, and we have therefore confined ourselves to indicating some of the directions in which improvement is possible. There seems to be unanimity amongst those who have given evidence before us as to the desirability of making patients who can afford to do so pay for their treatment at the clinics; but in view of the importance of encouraging attendance for treatment, we do not think that any compulsory

step can usefully be taken at present to secure this result.

Rural Areas.—We think it would be desirable, if a practical scheme could be worked out, that, with a view to providing treatment for patients in rural areas or districts where clinics are not easily available, a panel of medical practitioners should be constituted through whom treatment could be provided. This might be done by a development of the present system, under which a free issue of salvarsan substitutes is made to certain approved practitioners. It would have the further advantage of increasing the number of practitioners with experience in the treatment of venereal diseases.

Poor-law Patients.—Some evidence has been adduced before us in regard to Poor-law infirmaries, and we think it necessary to organise more thoroughly the methods which obtain at the present moment in Poor-law infirmaries for the treatment of venereal disease. It would, of course, be desirable from the medical point of view that those who enter Poor-law infirmaries suffering from venereal disease should be detained for treatment and cure, and indeed a recommendation to this effect was made by the report of the Royal Commission on Venereal Diseases, but the uncertainty as to the standard of non-infectivity and cure to which we have already referred seems to us a difficulty in such a measure. The same observation would apply to any proposal for the detention after the expiration of their sentences of prisoners found to be suffering from venereal disease. We doubt whether at present any more can be done than through the agency of social organisations, such as the Prisoners Aid Society and others, to endeavour to influence the sufferers to obtain and continue proper treatment at the clinics.

Special Classes.—In connexion with the spread of venereal disease we think that the close attention of the authorities concerned should be given to the following points:—

- (1) The entry into this country of persons suffering from venereal disease may be a serious source of danger.
- (2) The treatment of seamen suffering from venereal disease is a matter of great importance and requires special organisation.
- (3) There are found to be a considerable number of persons suffering from venereal disease among mental defectives, and the present arrangements for their control and treatment are inadequate.

CONCLUSIONS.

We do not in this report discuss many proposals which have been made to us with reference to alterations of the existing law with regard to venereal disease, as, for example, that it should be made a statutory offence knowingly to do any act calculated to expose any other person to infection, and the enactment of measures preventing the marriage of persons suffering from venereal disease. Such topics as these do not strictly fall within the terms of our reference.

We think that properly and promptly applied disinfection in the case of an individual man would almost certainly prove effectual, but that so far as the community at large is concerned, no sufficient case has been made to justify the introduction at the public expense of a general system of facilities either for self-disinfection or skilled disinfection, and wherever there is a limited amount of public money available, we have no doubt that money spent on—

- (a) Treatment of disease;
 - (b) Continuous education of the community in regard to the nature and dangers of venereal disease and the importance of seeking prompt and skilled treatment; and
 - (c) The elimination of those conditions of life which tend to foster promiscuous intercourse and the spread of disease
- will be money better spent than any money expended on establishing a general system for affording facilities for disinfection.

Local Liberty.—Notwithstanding what we have said above we are of opinion that it may well be that in certain areas special measures for the prevention of venereal disease would be justifiable, for example, measures for dealing with defaulters, or in a large

seaport town public ablution centres for disinfection in the neighbourhood of docks, and we think that local health authorities who are able to make to the Ministry of Health a special case for some such special measure should be allowed, at any rate for some limited period, by way of experiment, to carry out the measures they propose under the present system, by which a contribution towards the expense is made by the State. In this way there may ultimately be built up a body of experience of great value in determining future policy.

It is right to add that, so far as conclusions can be drawn from the available figures of attendances at clinics, venereal disease is once more, as it was before the war, substantially declining.

In this report we have directed our attention exclusively to syphilis and gonorrhoea. Soft chancre is a purely local affection, and does not exercise any sensible influence on public health.

The views and recommendations recorded above have been based on the existing medical knowledge as to the prevention and treatment of venereal diseases, and the Committee realise that certain modifications might be called for in the light of important new knowledge, of which there are indications.

The report ends with an appreciation of the services rendered by Mr. H. A. de Montmorency, of the Ministry of Health, who acted as secretary to the Committee.

PRESENTATION TO DR. BYROM BRAMWELL.

On the afternoon of May 19th a large company assembled in the Royal College of Physicians, Edinburgh, for the purposes of presenting portraits of Dr. Byrom Bramwell, one to himself, and another to the Royal College of Physicians. About 200 persons were present, including Lord Hunter, Lord Murray, Lord Salveson, Sir Alfred Ewing, Sir William Hale-White, Sir Archibald Garrod, Sir Percival Hartley, Sir Norman Walker, Prof. Lovell Gulland, Prof. Lorrain Smith, Dr. Farquhar Buzzard, Dr. William Hunter, Dr. Morley Fletcher, Dr. Stewart Fowler, Dr. G. S. Brock, Dr. John Thomson, Dr. Haig Fergusson, Dr. Michael Foster, Dr. Mackie Whyte, Dr. W. T. Ritchie, Dr. James Taylor, Mr. A. Gray Muir, Mr. James Watt, and Mr. John Gunn. The chair was taken by Sir Robert Philip, President of the College, who opened the proceedings by calling upon Dr. F. N. Kay Menzies, hon. secretary and treasurer of the Committee responsible for the arrangements in connexion with the presentation, to make a statement.

Dr. Menzies announced the receipt of over 30 letters of apology for absence from subscribers, amongst them being letters from the Lord Provost of Edinburgh, Sir Thomas Barlow, Sir James Crichton-Browne, Sir Dyce Duckworth, Sir James Purves-Stewart, Prof. Ashley Macintosh, and Prof. Musgrove. All of these subscribers, in addition to tendering their regrets at their inability to be present, expressed their great satisfaction that the appeal had been so successful, and their approval of the form of presentation upon which the Committee had decided.

Dr. Menzies read extracts from several of these letters. The total amount received, he said, had come to over £460, and subscriptions were still coming in. The subscribers numbered over 250; subscriptions had come from all parts of the British Isles, from Canada, South and West Africa, India, Burmah, Australia, New Zealand, and the United States of America. The original intention of the Committee was to confine itself to the presentation of a portrait of Dr. Bramwell from his medical friends and old students, but in view of the large number of subscriptions received it was felt that it would be an excellent plan to present another portrait of Dr. Bramwell to the Royal College of Physicians of Edinburgh, of which he had been so distinguished a president.

Sir Robert Philip expressed the appreciation of the Fellows of the College of the fact that the ceremony was taking place in that College, which had long been associated with Dr. Bramwell's work, and of which he was so distinguished a Fellow. It was their pleasure, he said, to have Dr. Bramwell here in fresh vigour and fullness of power. A high authority, after listening to and observing Dr. Bramwell on the previous night, had remarked: "If this be the man when he is over 70, I tremble to think what he must have been 40 years ago!" Sir Robert Philip closed his remarks with a reference to Dr. Bramwell as the embodiment of the ideal modern physician.

Sir David Drummond, in making the presentation, referred to his long knowledge of Dr. Bramwell, which dated from 1876; in 1878 they became colleagues as physicians on the staff of the Royal Infirmary, Newcastle-on-Tyne. This intimate association as a colleague was not to last, as Dr. Bramwell's ambition and his desire for wider fields as a physician and clinical teacher led him to that decision which robbed Newcastle and the North of England of his eminent services as a physician, and correspondingly enriched Edinburgh. Speaking in Edinburgh, it was unnecessary for him to enlarge upon Dr. Bramwell's great ability as a teacher, upon the esteem and affection, respect and admiration, in which he has been held by generations of students. As a worker Dr. Bramwell had always occupied the front rank of clinical investigators; his published works and his recorded cases had always commanded the confidence and careful attention of the profession, and his valued opinion as a physician had been sought far and wide. Dr. Bramwell's contemporaries were his debtors, and so would their successors be; the portrait would serve to show them what manner of man their benefactor was, whilst Dr. Bramwell's name would be perpetuated with added honour through distinctions won by his able sons.

Dr. Byrom Bramwell expressed in warm terms his thanks to his medical friends and old students, and, alluding briefly to his life-work, remarked that he looked back upon his teaching as one of the great joys of his life; it was a special gratification to him to know that his old students thought well of the time that they spent under his instruction in Newcastle and Edinburgh. He described himself as having been blessed beyond measure in his family life. It was, he said, a very great gratification to him to know that one of these portraits was to be given to that ancient Royal College of which at one time he had the honour of acting as President.

Sir Humphry Rolleston, in presenting the second portrait to the Royal College of Physicians, said that Dr. Bramwell's pupils welcomed the opportunity of expressing their admiration for a true clinical teacher of world-wide fame. Not only those who had had the privilege of daily personal contact with him, but the more numerous pupils who read his written teaching, welcomed that opportunity. To no physician teacher of the great Edinburgh School, during the last 30 or 40 years, had outsiders looked up as they looked up to Dr. Bramwell. In returning to Edinburgh 44 years ago Dr. Bramwell had done much to redress the balance of the debt that England owed to the Edinburgh School. To recite what he had done for medicine would be a task like reading an address on the modern advances of the last 40 years. The Sister College in London had done honour to herself by recently admitting him a Fellow under a special by-law for the election of medical men—not members of the College—who had distinguished themselves in any branch of the science or practice of medicine. Out of 367 Fellows there were 12 such only, and of this apostolic band Dr. Bramwell was the only clinician.

Sir Robert Philip gratefully accepted the portrait on behalf of the Royal College of Physicians of Edinburgh.

Dr. Robert Hutchison proposed a vote of thanks to the Royal College of Physicians of Edinburgh for allowing the gathering to have the use of their hall,

and also thanked the President for occupying the chair. Lastly, in the name of the subscribers, he thanked the artist, Mr. David Alison, who had so satisfactorily carried out the commission entrusted to him.

The proceedings closed with cheers for Dr. Bramwell.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Dail and the Dublin Hospitals.

A DEBATE took place last week in the Dail out of the vote of £16,738 for hospitals and charities. This sum is made up of grants voted at various times by the old Irish Parliament or the British Parliament in aid of various Dublin hospitals, and they are without system and proportion. The amounts bear no relation to the absolute or relative needs of the several hospitals. Mr. T. Johnson asked that the Ministers for Home Affairs and for Finance should consult in order to devise a method of financing the hospitals to a much greater extent. Mr. D. Figgis urged the appointment of a commission to reconsider the grants and treat the hospitals as primarily a public responsibility. Sir James Craig supported Mr. Figgis's demand and argued against any State control of the hospitals. He thought that State control would increase the expense and diminish the efficiency of the hospitals. He thought a commission ought to report on the financial position of the hospitals. Mr. Blythe promised that the whole matter would be considered very shortly, and not, as in the past, with one department looking after one section and another looking after another. A public health Bill was being drafted.

The Sweepstakes Bill.

The Public Charitable Hospitals Bill, generally known as the Sweepstakes Bill, came up in the committee stage before the Dail last week. After some debate it was referred to a select committee, with power to examine witnesses and call for papers and records. Enthusiasm for the Bill seems to have evaporated, and the reference to a select committee was spoken of—though not without protest—as a decent interment. It is worth noting that the promoter of one of the recent sweepstakes—while keeping his contract with the hospital concerned—admitted that the venture had not been over-successful.

A Forthcoming Census.

In the Dail last week the Minister for Local Government announced that it would be desirable to have a census soon. The census in Ireland has been due since 1921. Preparations were being made in that year to have the census taken at the same time as it was to be taken in Great Britain. The condition of the country was then so disturbed, however, that the authorities of the time wisely abandoned the idea of a census, which, if it were taken at all, would only have given misleading results. Since 1921 no favourable opportunity has occurred, but there seems to be no longer any reason for postponement.

BRITISH ORTHOPÆDIC ASSOCIATION: AN INTERNATIONAL MEETING.

THE meeting of the Association held at Leiden on May 24th was attended by 24 members from England and Ireland, and several Dutch visitors and one Austrian were present. The programme of scientific work was provided entirely by Dutch orthopædic surgeons and included the following short papers and discussions:—

Mr. Alvarez Correa: On Avulsion of the Axillary Nerve in Dislocation of the Shoulder.—On Multiple Enchondromata.
J. van Assen: Excision of the Obturator Nerve in Spastic Conditions.—Demonstration of an Orthopædic Operating Table.—Demonstration of an artificial leg.

W. F. Wassink: Demonstration of an instrument for directing Albee's peg in fracture of the femoral neck.—Reconstruction of the Socket-roof in the Hip-joint.
J. W. P. Fransen: On the Treatment of Neglected Congenital Dislocation of the Hip.

Murk Jansen: Demonstration of cases.—Clawfoot and its treatment.—Clubfoot in the Adult and its treatment.—Abdominal Pressure in the treatment of Deformities of the Spine.—Flattened Hip-socket and its Sequelæ.—Demonstration on how the plaster bed in side position is made.

Dr. Murk Jansen, of Leiden, met the members of the Association and arranged for their entertainment throughout the day. Most of them proceeded on the evening of May 24th to Amsterdam, where they attended the twenty-fifth anniversary meeting of the Dutch Orthopædic Association. This meeting was held under the presidency of Dr. Jansen and was of an international character. On May 25th the papers included one by Dr. Lorenz on an Operation for Untreated Congenital Dislocation of the Hip, by Sir Robert Jones on Orthopædic Experience During the War, by Dr. Calot on the Nature of Arthritis Deformans of the Hip, Dr. F. H. Albee on Bone Transplantation, Dr. Biesalski on the Physiological Treatment of Infantile Paralysis, Dr. Spitzky on the Surgery of the Joints, and Dr. Putti on Arthroplasty, in addition to eight papers by Dutch surgeons. On the morning of May 26th the meeting discussed the social care of cripples when the methods of organisation in the British Isles, Germany, Austria, America, and the Netherlands were described by representatives of these countries.

The British visitors were liberally entertained by their hosts in Holland. A largely attended dinner of the combined British and Dutch Associations was held at Amsterdam on May 25th, and on the following day the party was taken for a trip on the Zuyder Zee, visiting Marken and Vollandam. As the dam, which is to enclose a large section of the Zuyder Zee, will shortly be finished, this trip, which is very well known to visitors to Holland, will probably be impossible after the present year.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

R. R. Baker is entered as Surg. Lieut. for short service. Surg. Lieut.-Comdrs. to be Surg. Comdrs.: L. A. Moncrieff, A. C. Paterson, H. E. Scargill, and T. Cock.

Lt.-Col. P. H. Henderson, R.A.M.C., to be Asst. Director of Hygiene, vice Maj. and Bt. Lt.-Col. W. C. Smales.

ROYAL ARMY MEDICAL CORPS.

Maj. M. J. Cromie, half pay list, late R.A.M.C., retires on ret. pay on account of ill-health contracted on active service, and is granted the rank of Lt.-Col.

Maj. J. H. R. Winder to be Lt.-Col., to complete establt. Maj. and Bt. Lt.-Col. W. C. Smales relinquishes the temp. rank of Lt.-Col.

Maj. A. C. Osburn retires on ret. pay and is granted the rank of Lt.-Col.

The undermentioned Capts. retire, receiving a gratuity: H. H. Mulholland (granted the rank of Maj.) and M. McGee Russell.

Temp. Capt. C. K. O'Malley relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

General List: Capt. G. B. Tait, from 7th Bn., Middlesex Regt., to be Lt., and relinquishes the rank of Capt.

Capt. F. J. Lidderdale (late R.A.M.C.) to be Lt., and relinquishes the rank of Capt.

Capt. F. F. T. Hare and W. P. Moffet relinquish their commns. and retain the rank of Capt.

Capt. A. Wilson relinquishes his commn. and is granted the rank of Maj.

Capt. R. W. Aitken, having attained the age limit, is retired, and retains the rank of Capt.

INDIAN MEDICAL SERVICE.

Samuel Muffy to be temp. Lt.

The King has approved the retirement of Lt.-Cols. W. J. W. Brackenbury and W. Hesketh. Also of Capt. B. G. S. Clarke on account of ill-health.

Correspondence.

"Audi alteram partem."

DELAY IN GIVING DIPHTHERIA ANTITOXIN.

To the Editor of THE LANCET.

SIR,—Although the paramount importance of giving antitoxin in the early stage of the disease is well recognised by those who have seen much of diphtheria, there is evidence, unfortunately, that this fact is not so widely appreciated as it should be. A striking illustration is afforded by the experience obtained in one of the large metropolitan fever hospitals during the past year. Of 150 cases of diphtheria which proved fatal at this hospital during 1922, according to the report of the medical superintendent, no less than 46, or 30 per cent., died within 24 hours of admission, and 17 more, or 42 per cent., within 48 hours.

In view of the almost invariable success of antitoxin, if administered in the early stage of diphtheria, and the comparative harmlessness of the remedy, even should its use subsequently prove to have been unnecessary, this record must be regarded as nothing short of deplorable. In some instances the delay in securing a proper treatment is due to the failure of the patient's parents to call in a doctor, perhaps on account of expense, or, possibly, by reason of their not realising that he is ill. The general appearance of a diphtheria patient, especially in severe attacks, is occasionally very deceptive in the early stage, and even the medical attendant is apt to be misled, unless the throat be examined.

I am convinced, however, as the result of observations extending over many years of cases of diphtheria received into hospital, and a knowledge of the circumstances attending their removal, that the most frequent source of delay in treatment is the fatal practice of awaiting the result of bacteriological examination before deciding to give antitoxin, or sending the case into hospital. Hesitancy on the part of the practitioner to certify for removal before his diagnosis is confirmed is not unnatural, but the same objection does not apply to giving antitoxin. Until outside practitioners can be persuaded to administer serum on the mere suspicion of a case being one of diphtheria, the sad experience of patients being so frequently sent into hospital in a hopeless condition will continue to be a reproach to the profession.

It has been stated that a belief exists in the minds of a good many outside practitioners that the medical superintendents of the fever hospitals are averse to antitoxin being given to patients before they are sent into hospital. I do not know on what foundation this belief exists, if, indeed, it does exist, but I do know that the fact is quite to the contrary. Speaking on behalf of all my colleagues in the fever service, I am able to assert that if serum were to be given to every case of suspected diphtheria at the earliest possible moment before being sent into hospital, such action on the part of the certifying practitioner would be warmly welcomed. It is with the object of removing any misconception on this point which may exist that I venture to trouble you with this communication.—I am, Sir, yours faithfully,

F. FOORD CAIGER,

Chief Medical Officer, Infectious Hospitals Service,
Metropolitan Asylums Board.

London, S.W., June 1st, 1923.

IS DIABETES MELLITUS A PROGRESSIVE DISEASE?

To the Editor of THE LANCET.

SIR,—Prof. H. Maclean in the address published in your issue of May 26th states that "in human diabetes two factors are present: (1) An essentially progressive lesion absent in experimental animals;

and (2) the detrimental effect of improper diet." I doubt whether anyone who has studied diabetes mellitus will disagree with the second factor. There are some, amongst them the writer, who do not agree that diabetes is essentially progressive when the detrimental effect of an improper diet is removed. In some lectures delivered at the London Hospital I spoke of the conditions other than improper diet that lead to progress, several of which might awaken almost any obsolescent disease.¹

At the moment there are two camps: the belief in one is that correct diet will prevent progress of the disease; in the other, that however the diet be regulated the disease will progress. The first question which must be settled is this: Are the methods of regulating the diet adopted by the two camps identical? I do not know, and Prof. Maclean does not give me an opportunity of deciding. But I do know that it is not possible to find the correct diet by regulating it to prevent either glycosuria, or hyperglycæmia before meals. In my experience the diet which prevents the blood-sugar rising at any time above 0.15 per cent. arrests the disease, except in the conditions referred to above.

These two views were of considerable importance before the advent of insulin; now it is essential that crucial experiments be carried out to decide which is correct. If diabetes mellitus be essentially a progressive disease, comparatively little will be gained by correlating dose of insulin and diet to prevent hyperglycæmia, for in any case the pancreas will gradually deteriorate. On the other hand, if sugar in the blood be the stimulus to activity for the pancreas and overwork is the cause of the deterioration, then the diet and dose should be fixed to prevent hyperglycæmia at any time.

I am, Sir, yours faithfully,

Portland-place, W., May 29th, 1923.

O. LEYTON.

IS INFANTILE DEATH-RATE SELECTIVE?

To the Editor of THE LANCET.

SIR,—I have just read your leading article of March 17th with the above title, and I have also re-read Chapter XVI. of Prof. Raymond Pearl's monograph from which you quote, and I am still of the opinion that he justifies what you call his "dogmatic" statement. Your criticism is based on two arguments: (1) That partial correlation coefficients are not reliable, and (2) that there are wide differences of infantile mortality in differing districts which must be ascribed to differences of environment. I am surprised that no statistician has written in defence of partial correlation coefficients (having due regard to probable error and the possibility of spurious correlation), and I will not pretend to the necessary mathematical knowledge to do so myself. But the second argument appears to me to miss the mark.

Take a hypothetical case. Suppose two batches of ten boys of exactly similar hereditary constitution. One batch is sent to a school where no epidemic occurs, the other to a school where there is a severe epidemic of diphtheria. The first batch all survive, but six of the second get diphtheria, and two die. Now, the facts that there is a markedly different death-rate between the batches and that proper precautions might have prevented that epidemic of diphtheria, have surely nothing to do with the question whether or no the diphtheria acted selectively upon the six who were taken ill!

However, though Prof. Pearl is happy that truth should be vindicated, there is no reason why welfare workers need be unhappy about it. They may certainly be preserving lives which are destined to be below the average in duration, but not necessarily in value. As a race we have no ground for fearing that their efforts will do us harm; our expectation of life is all the time forming a more and more satisfactory curve from the sociologist's point of view.

¹ Brit. Med. Jour., April 28th, 1923.

Let the welfare worker reflect that it is worth while to preserve short lives like that of R. L. Stevenson even though we boast fewer picturesque but toothless centenarians as a result.

And I daresay Prof. Pearl would think so too.

I am, Sir, yours faithfully,

Saranac Lake, N.Y., U.S.A., May 14th. J. ROSSLYN EARP.

PRACTITIONERS AND COLLOID MEDICATION.

To the Editor of THE LANCET.

SIR,—As one, at all events, who requested you to publish the special articles now called "Modern Technique in Treatment," I beg to offer my hearty expression of appreciation of these articles. May I make a further suggestion for your consideration. We general practitioners are almost daily bombarded with literature as to colloid therapeutic measures—often fortified by statements of not altogether disinterested knights in the profession. Organotherapy is also thrust upon us with reiteration. If some

credible authority could give us information as to whether these colloids are really colloids and of any value at all, and also as to whether endocrinology is anything more than a fee-catching bait of the Harley-street specialist, it would help to dissipate the fog of charlatanism that unceasingly enshrouds us. Thanking you for past favours.—I am, Sir, yours faithfully,
Charing, Kent, June 1st, 1923. H. E. LITTLEDALE.

*** Sir William Bayliss dealt with the first of the two subjects in a special article published in THE LANCET last year (1922, i., 38). A full report of a recent discussion at the Section of Pharmacology and Therapeutics of the Royal Society of Medicine, and a leading article in the next issue (1923, i., 130 and 191) serve to distinguish the scientific investigations into the important subject of endocrinology from the attempts—sometimes too hasty—to find a practical application of these in organotherapy. We agree with our correspondent that these are subjects which might well be referred to, and which, indeed, call for further ventilation.—ED. L.

Obituary.

JOHN CHIENE, M.D., F.R.C.S., F.R.S. EDIN.,
D.Sc. SHEFF., LL.D. EDIN. & GLASG.,
EMERITUS PROFESSOR OF SURGERY IN THE UNIVERSITY
OF EDINBURGH.

THE death of Prof. Chiene on May 29th at an advanced age removes a surgeon who had played a great and worthy part in the Edinburgh school. John Chiene was born on Feb. 25th, 1843, the fifth son of George Todd Chiene, of Edinburgh. He studied medicine at Edinburgh and Paris, graduating M.D. Edin. and taking the F.R.C.S. Edin. two years later. In 1869, when Lister was appointed professor of clinical surgery, Chiene, who had previously been senior demonstrator of anatomy, was on the junior surgical staff of the Royal Infirmary and was one of his first and most loyal supporters. In 1882 Chiene became himself professor of systematic surgery, a post which he held for 27 years. When the South African War broke out Chiene was appointed consulting surgeon to the Field Force; he was mentioned in despatches, awarded the medal, and gained a C.B. Edinburgh and Glasgow Universities honoured him with the LL.D., Sheffield with the D.Sc., the surgical associations of America, Paris, and Finland made him an honorary member, and he presided at different times over the Royal Medical Society and the Royal College of Surgeons of Edinburgh.

In order to appreciate fully the important part which Chiene played in the development of the Edinburgh School of Medicine, it is necessary to realise how well he was qualified by education and temperament for assisting in the great revolution in surgical practice which was brought about by Lister. As a student Chiene was fortunate in having had as his teachers some of the foremost men of their day at a time when the Edinburgh school was very strong. Syme had taught him, on the one hand, the importance of realising the general principles which underlie any practical method, and, on the other hand, the value of simplicity in the manner of carrying out that method. From Goodsir he had imbibed a deep interest in anatomy, not merely from a practical, but also from a philosophical point of view. As a demonstrator in the dissecting room, under Goodsir, he had learned to teach directly from nature and to demonstrate his facts clearly. The professor of physiology (Hughes Bennet) had impressed him with the need for following in the van of advancing science in its application to practical medicine and surgery. With such a training Chiene readily fell under the spell of Lister's genius when he succeeded Syme in the chair of clinical surgery. At that time the antiseptic system of surgery, recently inaugurated in Glasgow, was fighting an uphill battle for recognition. The older surgeons in Edinburgh, as in other places, could see nothing of any value in

Lister's "new-fangled ways" of treating wounds, and if a few tried carbolic acid as a new kind of lotion, it was without appreciation of the all-important principle of organismal infection. Chiene was then an assistant surgeon in the Royal Infirmary and an extra-mural lecturer on surgery with an increasing popularity. He had many opportunities of influencing the minds of the undergraduates, and he did so to good purpose.

After Lister's removal to London and his own appointment, in succession to Spence, to the chair of systematic surgery, Chiene was still as ardent a follower of Lister as before, and was ready to develop new methods of teaching in the increased scope which the professorial chair provided. He opened a research laboratory—the first of its kind—in connexion with his department, and in addition to his success as a teacher he attracted students to the University by the fame of his classes in operative and practical surgery. He was, withal, a cautious and safe operator, careful of the interests of his patient. In the lecture room he laid stress on broad principles, explained them, when possible, by diagrams on the blackboard, and drove them home by simple illustrations which were telling and easily remembered. At this time he published his two books on surgical anatomy and operative principles. His style was natural and direct and embodied the advice given by Ruskin to authors in the following extract which Chiene was fond of quoting. "Certainly it is excellent discipline for an author to feel that he must say all that he has to say in the fewest possible words, or his reader is sure to skip them; and in the plainest possible words, or his reader will certainly misunderstand them. Generally, also, a downright fact may be told in a plain way, and we want downright facts at present more than anything else."

In the classroom, in the hospital, and elsewhere, Prof. Chiene was essentially an approachable man, ready to listen to students' difficulties, to explain them when he could, receptive of new ideas. He supported the athletic club and encouraged its members by his presence on the playing fields and at the annual sports. In all these ways he was a true friend to the school and his personality and teaching will be remembered with gratitude and affection by old students in all parts of the British Empire.

Prof. Chiene married in 1869 Elizabeth Mary, daughter of David Lyall, of Calcutta, by whom he had a daughter and two sons; one of the latter followed in his father's steps and is now lecturer on clinical surgery in Edinburgh University.

HENRY TROUTBECK, M.B., B.Ch. CAMB.

Dr. Troutbeck, medical officer to the Western Dispensary, Westminster, and to Westminster School, died suddenly on June 3rd at his residence in Ashley-gardens, London, S.W., of angina pectoris. He diagnosed his own condition in his last moments with extraordinary fortitude, pointing out that a post-

mortem inquiry would be needless. The second son of Dr. John Troutbeck, chaplain in ordinary to Queen Victoria and precentor of Westminster Abbey, he took the second place in the Natural Science Tripos at Cambridge in 1886. His clinical studies were taken at St. Bartholomew's Hospital, where, after qualifying in 1892, he held house appointments, and at the East London Hospital for Children at Shadwell. While at Cambridge he was a junior demonstrator in physiology. Dr. Troutbeck was well known in Westminster, where he was esteemed by all classes and especially by the poor, to whom his services were freely given. Last year he stood for the city council of Westminster and headed the poll.

ROBERT JOHN EWART, M.D., M.Sc. VICT.,
F.R.C.S. ENG., D.Sc. LOND., D.P.H.

WE regret to announce the death of Dr. Robert J. Ewart, medical officer of health for Barking, following an operation at the West Ham Hospital. He was in his forty-seventh year, having been born in Liverpool, the son of Edmund Brown Ewart, B.A., and educated at Liverpool Institute and University. As a student he won a number of distinctions, being Holt Tutorial Scholar and Junior Lyon Jones Scholar, becoming later Holt Fellow of Pathology in the University. After holding a resident appointment at the Liverpool Royal Infirmary and obtaining his F.R.C.S. Eng., he

gained his public health experience at Ashton-under-Lyne, going on to Middlesbrough as assistant M.O.H. and school medical officer. After appointment as medical officer of health to the Urban District of Barking he showed himself a very active and diligent public health officer, interested both in the preventive and epidemiological side of his work, with a philosophical bias which produced such essays as "Time and the Second Generation" and "Parental Age and Offspring." He was the author of a series of valuable papers dealing with the statistics of scarlet fever and diphtheria, which appeared in the *Journal of Hygiene*. His latest work on the Economics of Tuberculosis, presented early this year to the Royal Society of Medicine, was an excellent example of the capacity for condensing a wealth of statistical research into a small compass.

Dr. Ewart lost no opportunity of dwelling upon the importance of the food of the people to the public health, and saw in disease a pathological reaction due to faulty metabolism. No subject was too difficult for him to tackle, and even with imperfect data his originality of mind was able to elucidate the problems before him. Essentially unselfish, he possessed the true spirit of research, and his friends remember gratefully his willingness to share any information he possessed, even though he might not yet have published it himself. To the public health service his loss is a considerable one, for much was hoped from him.

Medical News.

UNIVERSITY OF LONDON: *Thomas Smythe Hughes Medical Research Fund*.—The Senate will proceed shortly to consider applications for grants from this Fund, which are allocated annually for the purpose of assisting original medical research. Applications must be received not later than June 15th, and must be accompanied by the names and addresses of not more than two persons to whom reference may be made. Further particulars may be obtained from the Academic Registrar.

At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Honours.—Una Christina Garvin (c) and Winifred M. Gray (d), Lond. Sch. of Med. for Women; Dulcie H. Lukis (a, c), Lond. Sch. of Med. for Women and St. Mary's Hosp.; and David H. Patey (d, e, University Med.), Middlesex Hosp.

(a) Distinguished in Medicine.

(c) Distinguished in Forensic Medicine.

(d) Distinguished in Surgery. (e) Distinguished in Midwifery.

Pass.—Elsa V. Adams, London Sch. of Med. for Women; Sarah E. Andrews, Westminster Hosp.; Ormonde A. Baker and John C. Blake, Univ. Coll. Hosp.; Gladys L. Buckley, London Sch. of Med. for Women; Khorshed Sorabji Captain, Grant Med. Coll. and London Sch. of Med. for Women; Gertrude B. G. Carden and Eva D. Cook, London Sch. of Med. for Women; Daryll C. Corry and Eleanor M. Creak, Univ. Coll. Hosp.; Avabai Jhangirji Dodhi, London Sch. of Med. for Women; Alfred H. G. Down, Univ. Coll. Hosp.; Helen W. Duncan, Univ. of Liverpool; Vivian Feldman, Univ. Coll. Hosp.; Ronald K. Ford, London Hosp.; Christine P. Francis, King's Coll. Hosp.; Arthur J. Gardham, Univ. Coll. Hosp.; Percy C. C. Garnham, St. Bart's Hosp.; Frank A. Gaydon, St. Thomas's Hosp.; Gerald N. Golden, London Hosp.; Evelyn E. Gourlay, London Sch. of Med. for Women; Edward E. D. Gray, Guy's Hosp.; Gwenvron M. Griffiths, London Sch. of Med. for Women; Charles F. Harris, St. Bart's Hosp.; Marjorie F. Hayward, Evelyn N. Heather, and Nancy M. Ifield, London Sch. of Med. for Women; Edgar G. Housden, St. Thomas's Hosp.; Gilbert H. Howells, Univ. Coll., Cardiff, and St. Thomas's Hosp.; Dorothy M. Howgate, Margaret G. Jones, Kathleen H. B. King, and Edna I. Langston, London Sch. of Med. for Women; Basil L. Laver and Ernest A. Levisour, Guy's Hosp.; James L. Livingstone, King's Coll. Hosp.; William E. Lloyd, St. Bart's Hosp.; Barbara V. Lucas, London Sch. of Med. for Women; Alison N. Macbeth-Morland, Univ. Coll. Hosp.; Alan C. Maconie, St. Bart's Hosp.; Norman S. Macpherson, St. Thomas's Hosp.; Rupert A. Madgwick, London Hosp.; Phyllis M. Manson, Edith T. Marshall, and Mary Michael, London Sch. of Med. for Women; John B. G. Muir, Middlesex Hosp.; Ruth N. Parker-Gray, London Sch. of Med. for Women; Gulbai Pirojsha Patel, Grant Med. Coll. and London Sch. of Med. for Women; Enid M. Powell, Charing Cross Hosp.; Muriel Rawlinson, London Sch. of Med. for Women; Dorothy S. Russell, London Hosp.; Emily V. Saunders-Jacobs and Cyril D. Shapland, Univ. Coll. Hosp.; Francis G. A. Smyth, St. Bart's Hosp.; Emma M. Store, London Sch. of Med. for Women; Richard O. Swaine, Middlesex Hosp.; Alexander Walk and William R. Ward, St. Bart's Hosp.; Cicely Weatherall, London Sch. of Med. for Women; and Hubert N. Williams, Univ. Coll. Hosp.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—B. Basuny, Middlesex Hosp.; W. A. Drake, Leeds; E. W. Hicks, St. Thomas's Hosp.; L. K. Htoe (Sect. I.), London Hosp.; W. J. Jameson, Albany Med. Coll., U.S.A.; C. S. Laurence, Sydney and Bristol; and J. Totton, Guy's Hosp.

Medicine.—B. Basuny (Sect. II.), Middlesex Hosp.; A. J. Dowek, Manchester; A. Gullertein, London Hosp.; and M. Hawke and J. Totton, Guy's Hosp.

Forensic Medicine.—W. A. Drake, Leeds; O. Sinanides, Athens; M. A. E. Somers, Bristol; and B. Zeitoun, King's Coll. Hosp.

Midwifery.—W. J. Jameson, Albany Med. Coll., U.S.A.; W. R. H. Pooler, Cambridge and St. Mary's Hosp.; and A. Vasudev and H. Whitby, London Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: B. Basuny, M. Hawke, W. J. Jameson, C. S. Laurence, J. Totton, and A. Vasudev.

DINNER TO SIR HENRY GRAY.—On the occasion of his leaving Aberdeen, to become chief of the surgical staff of the Royal Victoria Hospital, Montreal, a complimentary dinner is to be given to Sir H. M. W. Gray by his medical friends on June 27th, at 7.15 P.M., in the Palace Hotel, Aberdeen. The secretary of the committee in charge of the arrangements is Mr. W. Anderson, 5, Albyn-terrace, Aberdeen.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Under the auspices of the Fellowship of Medicine the Prince of Wales's General Hospital (N.E. London Post-Graduate College), Tottenham, will hold a two weeks' refresher course from June 11th to 23rd. The course will include demonstrations at affiliated hospitals and a clinical lecture daily at 4.30 P.M. At the "Children's Clinic," Western General Dispensary, Edgware-road, a course of eight lectures on Gastro-intestinal Diseases of Children will be given by Sir William Bayliss, Dr. Bernard Myers, and Mr. E. T. C. Milligan on Mondays and Thursdays at 5 P.M., beginning on Monday, June 11th. Other special courses during June will include one in Neurology at the West End Hospital for Nervous Diseases from June 25th to July 20th, a course in Ophthalmology at the Royal London Ophthalmic Hospital, and in Dermatology at St. John's Hospital for Diseases of the Skin, both beginning on Monday, June 11th. These courses will consist of lectures and clinical demonstrations each day in the wards and out-patient departments. The programme for July will include a two weeks' refresher course at the Royal Northern Hospital in conjunction with the Central London Ophthalmic Hospital and the Royal Chest Hospital from July 2nd to 14th, a fortnight's intensive course in Cardiology at the National Hospital for Diseases of the Heart, beginning on Monday, July 2nd, and a course on Dermatology at the Hospital for Diseases of the Skin, Blackfriars, from July 16th to 28th. For particulars application should be made to the Secretary, Fellowship of Medicine, 1, Wimpole-street, London, W. 1.

CHILD-STUDY SOCIETY.—A visit to Lord Mayor Treloar Cripples' Hospital and College, Alton, Hants, will be paid on Saturday, July 7th, when Sir Henry Gauvain will conduct the members over the hospital.

FEDERATION OF MEDICAL AND ALLIED SERVICES.—The report of the Executive Council of this body was presented at the annual general meeting of the members held on May 29th, at its offices, 12, Stratford-place, London, W. The report, which was adopted unanimously, showed considerable progress during the year, notably a valuable extension of work has been undertaken by coöperation with commercial and industrial firms, where the success has been largely due to Lord Islington and Sir Robert Kindersley. Among organisations accepting the services offered by the Federation and subscribing to its funds are the Prudential Assurance Co., the Royal Exchange Assurance, the Legal and General Assurance Society, the National Amalgamated Approved Society, the Liverpool Victoria Friendly Society, the National Federation of Employees Approved Societies, the Joint Committee of Approved Societies, the National Insurance Benefit Society, Messrs. Vickers, Ltd., Messrs. Debenham, Ltd., Messrs. Lever Bros., Ltd., Messrs. Oxo, Ltd., Messrs. Nestlé, Ltd., the Eastern Telegraph Co., the South Metropolitan Gas Co., the Gas Light and Coke Co., and Messrs. Shanks and Co. In order to deal promptly with the questions submitted by industry, the resources of the Federation have been augmented by an influential panel of specialists. A conference was held during the year on hospital finance, at which a representative gathering heard a discussion on many aspects of this difficult question from persons with special knowledge. The question of cancer research being taken up at a meeting of the Council, a resolution was carried unanimously calling upon the Government to allocate a large sum of money to cancer research, in view of the increasing mortality from this disease. The report states that this movement has resulted in the starting of the Empire campaign in which the British Red Cross Society has given invaluable assistance.

The income of the Federation for the first time showed a marked increase. Certain offices in the Federation, which were left vacant at the last annual meeting, have been fortunately filled by the securing of the assistance of Viscount Astor, Lord Islington, and Viscount Leverhulme as vice-presidents, with Sir Malcolm Morris who was elected last year; and Sir Robert Kindersley, a director of the Bank of England, as joint treasurer. Sir Berkeley Moynihan was unanimously re-elected President for the ensuing year, and Viscount Astor, Viscount Leverhulme, Lord Islington, and Sir Malcolm Morris were re-elected vice-presidents.

CONFERENCE ON INFANT WELFARE.—This conference will be held under the auspices of the National Association for the Prevention of Infant Mortality and National Baby Week Council at Carnegie House, 117, Piccadilly, London, W., on July 2nd, 3rd, and 4th. On the 2nd, at 10.30 A.M., Mr. Neville Chamberlain will give a presidential address, after which Mr. Eardley Holland, Dr. J. S. Fairbairn, Dr. Eric Pritchard, and Dr. R. C. Jewesbury will open a debate on the Causal Factors of Infant Mortality up to one year of age (ante-natal, intra-natal and post-natal) and their Prevention. At 2.30 P.M. a discussion on Maternity Homes and their relation to Maternal Mortality from Childbirth will be opened by Dr. W. Allen Daley. At 5 P.M. a meeting of the General Council of the Association of Infant Welfare and Maternity Centres will be held. On the 3rd, at 10.30 A.M., Dr. W. G. Willoughby and Dr. Mabel Brodie will open a debate on the Scope, Staffing, and Administration of Maternity and Child Welfare Centres, and at 2.30 P.M. Dr. E. W. Hope and Dr. F. E. Wynne will open a discussion on Is it Advisable in Urban Areas to Combine the Functions of the Health Visitor with those of other Officers of Local Authorities? The section of Maternity and Child Welfare Medical Officers of the Society of Medical Officers of Health will hold their annual general meeting at 5 P.M. On the 4th, at 10.30 A.M., Dr. Rhoda Adamson will open a discussion on the Maternity Resolution passed by the Washington Convention, 1919, and at 4.30 P.M. a discussion on Housing in relation to Infant Welfare will be opened by Miss M. M. Jeffery and Miss S. M. Bushell. For the benefit of all classes of infant welfare workers, six lectures will be given every evening during the conference, from 7 to 8 and from 8 to 9 P.M. These will include lectures on the Preservation of the Teeth, by Dr. C. E. Wallis; An Account of some Special Work in Huddersfield for the Reduction of Infant Mortality, by Dr. S. G. Moore; and the Prevention of Blindness in Young Children, by Mr. Bishop Harman. Arrangements will be made for conducted tours by motor, free of charge, to a considerable number of typical maternity and child welfare institutions of various kinds in London. Further particulars may be obtained from the hon. sec., Miss J. Halford, at 117, Piccadilly, London, W. 1.

Parliamentary Intelligence.

HOUSE OF LORDS.

WEDNESDAY, MAY 30TH.

Mental Treatment Bill.

THE House went into Committee on the Mental Treatment Bill, the Earl of DONOUGHMORE, Chairman of Committees, in the chair.

On Clause 2, which deals with the extension of powers of visiting committees,

Earl RUSSELL moved an amendment to give power to visiting committees to pay, if necessary, for the medical certificates that were required for recommendation for treatment. He had been asked to move this amendment on behalf of the London County Council. It was not desired that the committees should pay in all cases, but only where the persons themselves were unable to do so.

The Earl of ONSLOW said that with regard to the payment of expenses for securing a recommendation for treatment by two medical practitioners he should like to have an opportunity of considering it in conjunction with the noble lord, and perhaps they might then devise an amendment to Clause 7 which would cover this point and also the question of expenses incurred in conveying patients to and from institutions.

Earl RUSSELL said that he recognised that time was required to consider the matter.

The amendment was withdrawn.

The Earl of ONSLOW moved to omit from paragraph (5) of Clause 2, which deals with the power of visiting committees to undertake research in relation to mental disorder, the words "subject to and in accordance with a scheme to be approved by the Board of Control." He said that the London County Council had pointed out that this might be impracticable and that it was undesirable to submit an absolutely cut-and-dried scheme in regard to research work.

The amendment was agreed to.

On Clause 4, which deals with the temporary treatment of mental disorder without certification,

Lord PHILLMORE moved an amendment to provide that the consent of parent or guardian should only be valid as a substitute for the voluntary submission of the patient to enter an approved institution in the case of minors under the age of 16 years. He said that it seemed to him that in the case of people nearly grown up, boys and girls of 17 and 18 years of age, it was very undesirable that the machinery of the Bill should be used to enable a father or guardian to compel their admission into one of these institutions and keep them there until they came of age or until the father or guardian was pleased to allow them to come out. The law with regard to minors did not in its general principle authorise such constraint. Further, he would point out that marriage had always been considered as an emancipation; but under this Bill as it now stood a married woman of 18, 19, or 20 might, notwithstanding that her husband did not wish it and she did not wish it, be placed by the father in one of these institutions until the age of 21. He was sure that that could not have been the intention of the framers of the Bill. He understood that the only difference between him and the noble earl who represented the Government was that he (Lord ONSLOW) was rather doubtful whether 16 was not too young and whether it should not be 17 or 18.

The Earl of ONSLOW said that while the Government would not be averse from accepting the principle of the amendment they felt that 16 was a rather too early age at which to give this power, especially in view of the possible state of health of the person affected. They preferred the age of 18, but if the noble lord would withdraw the amendment the point might be considered again before the Report stage.

Lord PHILLMORE agreed, and the amendment was withdrawn.

On Clause 5, which deals with the discharge of persons detained in institutions under the Act,

Earl RUSSELL moved an amendment to provide that any person received as a boarder or patient in any institution might leave at any time upon giving the medical superintendent or other person in charge three days' notice instead of 48 hours as proposed by the Bill. He said he had been asked to move the amendment by those who were interested in administration, and who felt that 48 hours was very much on the short side. If such notice were given on Saturday at about midday it might be impossible to communicate with the patient's friends. Unless this amendment were accepted some patient might be discharged on a Monday morning without there being anyone to receive him, and, as one very experienced alienist wrote to him (Lord Russell), might be cut up on the railway line a few hours later.

The Earl of ONSLOW said he was impressed with the argument of the noble earl and he would accept the amendment.

if he would alter the period from "three days" to "seventy-two hours."

The amendment to substitute "seventy-two hours" for "forty-eight hours" was agreed to.

On Clause 8, which deals with the application of the Bill to London,

The Earl of ONSLOW moved an amendment to preserve the separate jurisdiction of the Corporation of London under the Act.

The amendment was agreed to.

The Earl of ONSLOW moved after Clause 8 to insert the following new clause: "Asylums provided by any public authority in England or Wales for lunatics or other persons of unsound mind shall hereafter be called mental hospitals, and accordingly for references in any public or local Act or in any Order, regulations, or other document issued under any such Act to any such asylum shall be substituted references to a mental hospital." He said that hitherto mental institutions had been described as asylums, and the word "asylum" had been associated with mental deficiency, and perhaps had contributed to the view that it was less a disease than an irremediable affliction. Nurses in mental institutions, alienists, and the Board of Control were anxious that this change of name should be adopted.

The amendment was agreed to.

The Committee stage was concluded, and the Bill as amended was reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, MAY 30TH.

Tuberculous Milk.

Mr. ADAMS asked the Minister of Health whether he was aware that the corporation of Newcastle-upon-Tyne, in their weekly examinations for tuberculosis in samples of milk sold for consumption in that city, found that the highest proportion of positive samples was 10.4 per cent. in 1912, and that during the period of cattle shortage and general control by the Government of slaughtering it fell steadily to 3.6 per cent. in 1919, but that since that year it had risen again, and by 1922 stood at the relatively high figure of 7 per cent.; and whether, in view of the fact that tuberculous milk is one of the prime sources of the disease of tuberculosis in the population, he would take or propose measures for more efficiently dealing with herds in rural areas by transferring the duties in connexion therewith from the small local authorities to combinations of these or to county councils.—Mr. NEVILLE CHAMBERLAIN replied: I understand that the facts are as stated. The duty of taking measures to prevent the sale of tuberculous milk was placed on county and county borough councils by the Milk and Dairies (Consolidation) Act, 1915, but the commencement of that Act has been postponed till Sept. 1st, 1925, by the Milk and Dairies (Amendment) Act, 1922. I may, however, remind the hon. Member that Section 11 of the Act of 1922 provides for the transfer to the county council of the powers and duties of a district council under the Act or any other enactments, orders, or regulations relating to milk and dairies, if the county council resolve that the district council have failed to exercise or perform any of those powers or duties and make complaints thereof to my department.

Agricultural Workers and Health Insurance.

Mr. SHEPPERSON asked the Minister of Health whether there were available data illustrating the average annual value of benefits received per worker among agricultural workers under the National Health Insurance scheme; and how this compared with the corresponding figure for workers in urban industries.—Mr. NEVILLE CHAMBERLAIN replied: As agricultural workers are distributed amongst many thousand approved societies and branches which are not, in general, organised on an occupational basis, it is impossible to give figures as to the annual value of benefits received by such workers throughout the country. An analysis of the figures of certain societies whose membership consists largely of agricultural workers shows a claims experience from 5 to 10 per cent. more favourable than that of societies generally, with the result that such societies have been placed in a position to provide their members with exceptionally favourable additional benefits.

Panel Practitioners' Remuneration.

Sir KINGSLEY WOOD asked the Minister of Health whether any conferences had recently taken place between representatives of the doctors on the panel list and his own department; whether any alteration in the terms of the panel service had been discussed; and whether it was proposed to revise the remuneration now being paid in respect of such service.—Mr. GILBERT asked the Minister of Health what was the present payment made to doctors under the Health Insurance Acts; whether any negotiations were proceeding with the doctors for the purpose of reducing the amount now paid annually per patient; what the proposed reduction amounted to; and if he could make any statement on the

subject.—Mr. NEVILLE CHAMBERLAIN replied: A conference has been held with the Insurance Acts Committee of the British Medical Association to consider certain modifications in the terms of service of insurance practitioners, but no discussion has yet taken place in regard to the rate of remuneration after the expiry of the present agreement, which fixes the rate at 9s. 6d., exclusive of payments in respect of drugs and mileage to rural practitioners.

Sir KINGSLEY WOOD: When this conference has taken place will the right hon. gentleman take steps to see that so far as it is possible to do so the panel service is improved, having regard to the very many objections and complaints that are coming from all parts of the country at the present time.—Mr. CHAMBERLAIN: Yes, Sir, that has been the subject of consideration.

Small-pox.

Mr. BECKER asked the Minister of Health the number of people who had died this year up to April 30th with small-pox; and, if any, what percentage of these were vaccinated and what percentage were unvaccinated.—Mr. NEVILLE CHAMBERLAIN replied: No deaths have so far been registered this year as due to small-pox.

Defence Forces: Coördination of Medical Services.

Replying to Captain WEDGWOOD BENN, Mr. GWYNNE (Financial Secretary to the War Office) said that the decisions of the Government in regard to the recommendations of the Committee on the Coördination of the Technical Services of the Navy, Army, and Air Force, so far as they affected the Medical Services, were as follows: (a) A joint committee consisting of the heads of the medical departments of the Navy, Army, Air Force, and Ministry of Pensions, together with such other persons as may be nominated by those departments, should be established to discuss matters affecting the Medical Services of the four departments. (b) The terms of reference of the committee should be to advise upon (1) important questions of medical policy such as the construction of new hospitals; (2) the provision of facilities for common training; (3) specifications for the supply of medical stores and appliances; (4) the use of Army, Navy, and Air Force hospitals for the accommodation of disabled war pensioners; and (5) all matters in respect of which economies might be effected by the coöperation of the four departments. A technical Coördinating Committee should be set up to meet at definite intervals to deal with medical and veterinary stores. Subcommittees should be appointed to conduct detailed investigations with regard to particular items of supply. The terms of reference should be to consider (1) the adoption wherever possible of trade standards and patterns for commodities and stores common to and in use by the three Services; (2) the standardisation wherever practicable of the specification and design of commodities and stores common to and in use by the three Services for which a trade pattern was unsuitable; and (3) the coördination of the methods and procedure of inspection. The Coördinating Committee should be composed of one or more representatives from each Service who should be technical officers of rank and experience and with a knowledge of Service practice.

THURSDAY, MAY 31ST.

Medical Treatment of School-Children.

The House went into Committee on a Vote of £25,934,047 for the salaries and expenses of the Board of Education and the various establishments connected therewith including sundry grants-in-aid, Mr. J. F. HOPE, Chairman of Committees, in the chair.

Mr. E. WOOD (President of the Board of Education) in explaining the Vote referred to the question of the physical well-being of school-children. He thought it was true to say that the value of the School Medical Service was being increasingly realised by all concerned—the taxpayers, the ratepayers, the parents, the teachers, and the authorities. The total cost for the results which they got was, he thought, not excessive, working out at 4s. 4d. per child on average attendance. He had made it his business to inquire of those who had opportunities of judging, such as the Board's medical officers, school teachers, members of after-care committees, and so on, as to the effect, if any, of the prolonged trade depression on the physique of the children, and he had been, he confessed, much relieved to learn from them that they did not think that the trade depression had adversely affected the condition of the children. The school medical officer for Hull reported that in spite of the depression children were taller and heavier in the several age-groups and fewer children were reported by the teachers as mentally backward than in any year since the armistice. For blind, deaf, and physically and mentally defective children provision could only properly be made through the medium of the special school. The attitude of the Board towards that question had excited a certain amount of anxious and legitimate concern, and he assured the Committee that he was as alive to the reactions of the problem as any Member of the House. The dominant reason why

there was a large number of children in this category for whom no provision was made was that the existing provision was so expensive that it had not been possible to develop it as they would wish. It was only by reducing the cost of these special schools to as low a figure as was compatible with efficiency that they could hope to make a substantial inroad into the great blocks of children at present being denied the benefits to which they were entitled. With that object he had directed that a review should be made into the standard of staffing and in other directions to see whether they could get comparatively the same efficiency at a slightly less cost.

Mr. MORGAN JONES, in moving the reduction of the Vote by £100, said the figures with regard to defective children were staggering. There were something like 10,000 mentally defective children in the schools, and there were, it was estimated, 2500 mentally defective children in no schools at all. There were 74,000 physically defective children in the schools and 14,000 in no schools at all. Any attempt to arrest the development of these special schools for cases of this specially deplorable type would have the most disastrous consequences for the community as a whole, and would only involve further provision of a more expensive kind at a later date.

After further discussion progress was reported.

Drunkenness Due to Methylated Spirit.

Mr. RHYS DAVIES asked the Secretary of State for the Home Department how many cases of drunkenness due to drinking methylated spirit had been reported during the past year; what proportion of these cases were amongst women; whether the figures indicated an increase in the habit of drinking methylated spirit on the part of women; what steps he was taking, or proposing to take, to stop this practice, either by increasing the difficulty of procuring methylated spirits, or by the addition of some other ingredient which would more effectually prevent its use for this purpose.—Mr. BRIDGEMAN replied: The number of cases in England and Wales in the year 1922 in which the condition of the person convicted of drunkenness is reported to have been due to the drinking of methylated spirits is 516—250 males and 266 females. These figures are higher for both males and females than similar figures for the previous two years, and the greater rate of increase is shown by the males. The figures have been collected for only three years yet, and some part of the increase may be due to improvement in reporting. I am watching the matter carefully, but at present I have nothing to add as regards the possibility of further preventive measures to the answer I gave on March 14th.

Panel Practitioners' Records.

Dr. WATTS asked the Minister of Health if he was aware that under their present agreements panel doctors were compelled to keep records of their attendances and of illnesses of their patients, which involved a great amount of clerical work and took up much time which might be occupied in examining their cases; and would he, in framing the new terms of service, abolish these records.—Lord E. PERCY replied: My right hon. friend cannot accept the suggestion implied in the hon. Member's question that the keeping of the prescribed simple form of record need interfere in any way with the proper examination of patients, and he is not prepared to assent to the abolition of the record card.

Sale of Machine-skimmed Milk.

Mr. LAMB asked the Minister of Health whether his attention had been directed to an advertisement of Milkal, household milk, which was described as machine-skimmed milk from which only the water had been eliminated; and whether, in view of the implied suggestion that only the water had been eliminated and not the butter-fat, he would say what action he proposed to take for the protection of the consumer who might not be aware of what was actually removed by the process of machine skimming.—Lord E. PERCY replied: Yes, Sir, my right hon. friend's attention has been drawn to the advertisement in question and he agrees that it is likely to mislead readers as to the nature of the article advertised. He has no power to take action with regard to such advertisements, but he is considering regulations to provide for the proper labelling of dried milks.

FRIDAY, JUNE 1ST.

Medical Women and Board of Control.

Sir ROBERT NEWMAN asked the Minister of Health how many medical men and how many medical women were commissioners of the Board of Control; and how many medical men and how many medical women held the position of inspector under the Board of Control.—Mr. NEVILLE CHAMBERLAIN replied: There are four medical men who are commissioners of the Board of Control and two medical men inspectors; there are no medical women either as commissioners or inspectors.

MONDAY, JUNE 4TH.

Choice of a Panel Doctor.

Mr. SNOWDEN asked the Minister of Health what was the total sum paid out in each of the last three completed years under the National Health Insurance scheme by societies for members who had not selected panel doctors; and by what amount the panel doctors had benefited each year over and above the fees agreed upon through the action of those who had not selected a panel doctor.—Lord E. PERCY replied: The hon. Member is under some misapprehension. The right to medical attendance is not affected by the insured person's previous neglect to choose a doctor. Insured persons not infrequently put off selecting a doctor until they become ill, but they have a right to treatment immediately they are in need of it, irrespective of whether they are at the time on any doctor's list. The panel practitioners, therefore, are collectively at risk in respect of all insured persons entitled to medical benefit. The actual number of unassigned persons, which cannot be precisely calculated, is roughly 700,000, but the proportion of these who do not avail themselves of their right to treatment when they need it is a relatively small and diminishing number. My right hon. friend has no information as to the distribution of unassigned persons between different societies.

Cancer Research.

Mr. ALFRED T. DAVIES asked the Minister of Health whether it was intended to grant further financial and expert aid towards research in connexion with the ravages of cancer; and what assistance was now given to such research.—Lord E. PERCY replied: Financial assistance is at present given from public funds to cancer research through the Medical Research Council, who, in the last financial year, expended a sum of approximately £5000 for this purpose in addition to further large sums assigned to the support of other investigations not specifically directed towards the problem of cancer, but which may nevertheless provide the desired clues. The Council hold on behalf of the Government a valuable stock of radium salt, of which fractions are in use for cancer research work at 11 different universities or hospitals in Great Britain and Ireland under a co-ordinated scheme. Expert advice and assistance are provided as required through the Council, and I may add that a special departmental committee was appointed by my right hon. friend in January last to survey the whole question and consider how the medical and administrative resources of the Ministry can best be utilised in the campaign against cancer. The whole subject is continuously under review, and the question of further financial and expert aid will be considered from time to time as experience may show that they can be usefully given.

TUESDAY, JUNE 5TH.

Pensions Administration.

The House went into Committee of Supply on a vote of £73,655,246 for salaries and expenses of the Ministry of Pensions and sundry contributions in respect of the administration of the Ministry of Pensions Act, 1916, and the War Pensions Acts, 1915 to 1921, Mr. J. F. HOPE, Chairman of Committees, in the chair.

Major TRYON (Minister of Pensions) said that the highest point of expenditure of the Ministry was reached in November, 1919, and since then there had been a continuous and steady decline. During the last few months, however, the decline had been slowing down. The reduction last year was 13½ per cent.; this year it would be about 10½ per cent. The actual reduction in the cost of the Ministry this year was £8,844,754, due to decreases in the cost of administration and in the cost of pensions. The number of the paid staff was at its highest in July, 1920, when it was 32,091; this year it was 23,552. Of the men employed 97 per cent. were ex-Service men. Dealing with the criticism of medical boards the right hon. gentleman said if those boards were stopped the men who were getting worse would not receive more, and the men who were getting better would receive more than they ought to. But the change due to medical boards was getting less and less, and it was not the case that they were cutting down pensions rapidly. The charge that secret instructions had been sent out that pensions should be cut down had been inquired into by a Committee which included a number of ex-Service men, and that committee came to the unanimous decision that the story was untrue. Ninety-five per cent. of the doctors on the boards were ex-Service men. In regard to stabilisation the policy of the Ministry must be directed towards the stabilisation of awards. He desired to cut down as much as possible the checking and reopening of cases, and he had been able, with the consent of the Treasury, to arrange to bring the review to a close at the end of the financial year. A change of medical opinion alone would in no case thereafter suffice to justify a change of entitlement.

Mr. MACPHERSON, who moved to reduce the vote by £100, said he was anxious that the convalescent centres should be continued and developed, and clinics should be established in every big town to which after working hours men could go and find the best medical treatment obtainable. During the last three years the State had spent no less than £58,000,000 on medical treatment. It had willingly spent that amount, but in justice the State ought to get a return, and the only return was that as many men as possible should be made healthier and stronger. He would like to be assured that in cases where a man had been given a final award and got ill again that the State should give him his previous treatment. He did not believe the criticism which was levelled against the medical boards, and according to his experience those boards were doing their work well. But it was being said that some boards were wrong in their diagnosis and ruthless and rough in their treatment of pensioners. That was a state of things which, if true, the country would never tolerate, and he thought that the Ministry ought to reassure themselves by making an immediate and effective investigation into complaints. He took the view that only in exceptional cases pensions should be commuted. He was in favour of the seven years' limit, which seemed to him quite fair. In other countries the limit was only two years. There were still, he regretted to say, about 300 ex-Service men in asylums, and if there was any way of proving that their disease had been contributed to by war service the Minister would receive the support of everyone in seeing that these men got their rights.

After further debate,

Captain CRAIG (Parliamentary Secretary to the Ministry of Pensions) dealing with medical treatment, said that the total estimated cost of medical services for 1923-4 was £5,083,000. Of that sum £3,797,000 represented medical treatment and £1,286,000 represented boarding and administration. There was a reduction this year of £1,503,000. On June 30th, 1920, there were 146,000 men under treatment, 155,000 in 1921, 110,000 in 1922, and on March 31st this year 80,000. He repudiated the suggestion that the doctors who served on the medical boards had any bias against ex-Service men. These doctors had been practising in the various districts for years, and practically all of them were still carrying on their ordinary work. It was ridiculous to suppose that they could be prejudiced in their dealings with ex-Service men. The Ministry were always ready, and only too anxious, to adopt any new treatment which had been proved satisfactory. Among others they had adopted the insulin treatment for diabetes. They had also taken advantage of the latest knowledge with regard to the treatment of tropical diseases. One of their most wonderful achievements was in regard to cases of severe facial injury, which were treated at Sidcup. A considerable amount of surgical work was unfortunately still necessary. Cases were constantly occurring where wounds, which had been apparently quiescent for as long as two or three years, broke out again, and in some cases had so affected the bones that the amputation of limbs was necessary. Since Jan. 1st 302 men discharged from the Army with limbs had had amputations. The British Legion had for some time urged upon the Ministry the desirability of separate accommodation for the treatment of mental cases resulting from war service. Accommodation for 300 patients had been secured in an institution in the West of England, and cases were being sent there as rapidly as possible. Already from 50 to 100 cases were in that institution, and further accommodation would be secured elsewhere. With regard to village settlements for tuberculous ex-Service men, they hoped that within a short time they might set some of those settlements in full swing in order that their utility might be tested.

Major TRYON, in winding up the debate, explained that he had decided that in future there should be no time limit in the way of a widow of a pensioner drawing a pension at the full rate if her husband's death be shown to be the result of war service. This applied whether the pension was under 50 per cent. or over it.

Mr. Macpherson's amendment was negatived by 273 votes to 128 and the vote was then agreed to.

Dr. Arthur T. Davies has been elected an honorary member of La Société d'Histoire de la Médecine, Paris.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—On the retirement from the presidency of the Association of Prof. George M. Robertson, of Edinburgh, Dr. Michael J. Nolan, of Down District Asylum, Downpatrick, Lord Chancellor's Visitor in Lunacy for the Belfast district, was elected to succeed him.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Thursday, June 14th.

NEUROLOGY: at 8.30 P.M.

Paper:

Dr. L. R. Yealland: Hysterical Fits with Some Reference to Their Treatment.

Friday and Saturday, June 15th and 16th.

LARYNGOLOGY.

Summer Meeting at the Royal Infirmary, Manchester.

Friday, June 15th.

Morning: Reading of papers.

Afternoon: Demonstration of Cases. Annual Dinner at Clarendon Club, at 7.30 P.M.

Saturday, June 16th.

Demonstrations and Operations at the Royal Infirmary and elsewhere.

(For details see special circular.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

The Croonian Lectures have been postponed owing to the regretted illness of the lecturer.

FELLOWSHIP OF MEDICINE POST-GRADUATE LECTURES, 1, Wimpole-street, W.

WEDNESDAY, June 13th.—5.30 P.M., Mr. James Berry: The Dyspnoea Caused by Goitre.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, June 11th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10 A.M., Mr. Steadman: Dental Dept. 2 P.M., Mr. Banks-Davis: Nose, Throat, and Ear. 2.30 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—11 A.M., Mr. Simson: Gynaecological Demonstration. 12.15 P.M., Dr. Burnford: Medical Pathology. 2.30 P.M., Mr. Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—10 A.M., Dr. Drummond Robinson: Gynaecological Operations. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear. 3 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Nose, Throat, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham, S.W.

MONDAY, June 11th.—4.30 P.M., Mr. V. Cope: Demonstration of Surgical Cases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Lectures at 4.30 P.M.

MONDAY, June 11th.—Mr. H. W. Carson: The Early Diagnosis of Carcinoma of the Stomach.

TUESDAY.—Dr. A. E. Giles: Conservative Gynaecology.

WEDNESDAY.—Mr. J. Howell Evans: Some Congenital Intestinal Lesions. Illustrated by lantern slides.

THURSDAY.—Dr. L. R. Yealland: Pelvic Pain.

FRIDAY.—Dr. F. G. Crookshank: Diagnosis.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, West Smithfield, E.C.

TUESDAY, June 12th.—5 P.M., Dr. Andrew Balfour: Tropical Hygiene (1).

THURSDAY.—5 P.M., Tropical Hygiene (2).

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

WEDNESDAY, June 13th.—4.15 P.M., Dr. W. M. Feldman: Fœtal Physiology.

FRIDAY.—4.15 P.M., Mr. A. J. Walton: The Thyroid Gland.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, Paddington, W.

THURSDAY, June 14th.—4.30 P.M., Prof. G. Dreyer: Some New Principles in Bacterial Immunity: their Applications to the Treatment of Refractory Infection.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, June 14th.—4 P.M., Dr. Frew: Mental Deficiency.

INFANTS HOSPITAL, Vincent-square, S.W. 1.

TUESDAY, June 12th.—8.45 P.M., Dr. W. E. Robinson: Respiratory Disease in Infants.

FRIDAY.—8.45 P.M., Dr. N. O. Richards: The Hygiene of Infancy and the Role of the Welfare Centre in Relation to the General Practitioner.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, June 11th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Clinical Lecture: Dr. Aldren Turner.

TUESDAY, June 12th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Intracranial Complications of the Diseases of the Ear: Mr. Just.

THURSDAY, June 14th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Electrical Testing of Muscles: Dr. Bailey.

FRIDAY, June 15th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Muscular Atrophies: Dr. Saunders.

COURSE OF LECTURES ON NEURO-PATHOLOGY.

MONDAY, June 11th.—12 noon, Tissue Reaction in Disease of the Nervous System: Dr. J. Godwin Greenfield.

A COURSE OF 12 LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on TUESDAYS AND FRIDAYS if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the whole Course is £12 12s., including Anatomy and Physiology, but these Lectures may be taken separately for a fee of £4 4s. The fee for the Course without Anatomy and Physiology Lectures is £10 10s. Special arrangements as to fees will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, June 14th.—5 P.M., Mr. L. G. Phillips: Induction of Abortion.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

MONDAY, June 11th.—At Hereford, Prof. F. H. Edgeworth: Paroxysmal Paralysis of the Elderly.

Appointments.

SLOANE, J. M., M.B., B.Ch., B.A.O. Belfast, has been appointed Fourth Assistant Medical Officer, Knowle Mental Hospital, Fareham, Hants.

WALKER, E. H., M.B., Ch.B., D.P.H. Manch., Medical Officer of Health and School Medical Officer at Stretford.

Kensington, Fulham, and Chelsea General Hospital: BLOOM, H., L.D.S., and PAIN, A., M.R.C.S., L.D.S., Honorary Dental Surgeons.

St. Thomas's Hospital: STORY, A. G., M.R.C.S., L.R.C.P. Lond., COLE, L. B., M.B., B.Ch. Camb., GIBSON, C. P. R., M.R.C.S., L.R.C.P. Lond., FULLER, C. B. S., M.B., B.Ch. Camb., SUDBURY, F. B., M.R.C.S., L.R.C.P. Lond., DAVIES, D. A., M.R.C.S., L.R.C.P. Lond., HUGHES, K. E. A., M.R.C.S., L.R.C.P. Lond., and CROCKFORD, A. L., M.B., B.Ch. Camb., Casualty Officers and Resident Anaesthetists: GAYDON, F. A., M.R.C.S., L.R.C.P. Lond., BAIN, C. W. C., M.B., B.Ch. Oxf., LEYS, D. G., M.B., B.Ch. Oxf., and OLIVER, C. P., M.R.C.S., L.R.C.P. Lond., Resident House Physicians: DREW, J. G., M.R.C.S., L.R.C.P. Lond., Resident House Physician for Children: MACPHERSON, N. S., M.R.C.S., L.R.C.P. Lond., PATRICK, C. V., M.R.C.S., L.R.C.P. Lond., NICHOL, R. W., M.R.C.S., L.R.C.P. Lond., and CHURCHER, J. C., M.R.C.S., L.R.C.P. Lond., Resident House Surgeons: LUND, G. S., M.R.C.S., L.R.C.P. Lond., Resident Orthopaedic House Surgeon: WILLIAMS, E., M.R.C.S., L.R.C.P. Lond., and KIES, J. P., M.R.C.S., L.R.C.P. Lond., Resident House Surgeons for Ear, Nose, and Throat: SMALLEY, L., M.R.C.S., L.R.C.P. Lond., Senior Obstetric House Physician, and BERRIDGE, W. C. M., M.R.C.S., L.R.C.P. Vacancies.

For further information refer to the advertisement columns.

Acton Hospital, Gunnersbury-lane, Acton, W.—R.M.O. £125.

Bangor, Carnarvonshire and Anglesey Infirmary.—H.S. £200.

Birmingham and Midland Eye Hospital.—H.S. £120.

Birmingham, Queen's Hospital.—Hon. P's. Also Asst. Radiographer. £250.

Blackburn County Borough.—Asst. M.O.H., &c. £600.

Bootle Borough Hospital.—Hon. Gyn. S. Also Hon. S. to Ear, Nose, and Throat.

Bristol General Hospital.—H.S. £125.

Cairo, Kitchener Hospital for Women.—Female Res. M.O., £E.400.

Cancer Hospital, Fulham-road, S.W.—H.S. £100.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.

Charing Cross Hospital Medical School, W.C.—Pathological Chemist. £400.

Chiswick Hospital, Netheravon-road, Chiswick, W.—Consulting P. and Consulting S.

Derbyshire Royal Infirmary, Derby.—H.S. £200.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. £175.

Effe and Kinross Joint Sanatorium.—Res. Asst. M.O. £250.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.P., H.S., Cas. M.O., and Cas. S.O. Each £100.

Hayward's Heath Hospital.—Hon. Radiologist.

London County Mental Hospital Service.—Seventh Asst. M.O. £440.

London Lock Hospital, 91, Dean-street, W.—Clin. Assistantships.

Maidstone, Kent County Ophthalmic Hospital.—H.S. £300.

Manchester and District Radium Institute.—Asst. Radiologist. £400.

Manchester Children's Hospital.—Asst. S. £50.

Margate, Royal Sea Bathing Hospital.—Res. S. £200.

Metropolitan Ear, Nose, and Throat Hospital, 2, Fitzroy-square, W.—Senior Clin. Asst.

Oldham Royal Infirmary.—H.S.'s. Each £200.

Portsmouth Royal Hospital.—Sen. H.S. £200. Also Two Asst. H.S.'s. Each £150.

Preston, Lancs, Whittingham County Mental Hospital.—Pathologist Asst. M.O. £590 17s.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. Cas. H.S. £100.

Royal Northern Hospital, Holloway, N.—Ophth. S.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.S. £100.

St. Lucia, Victoria Hospital.—Res. S. £500.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clinical Assts.

Shanghai Municipal Council, Public Health Dept.—Radiologist. Taels 700 per mensem.

Sheffield Royal Infirmary.—Clin. Asst. £300.

Sheffield, South Yorkshire Asylum.—M.O. £400.

Sudan Government, Medical Dept.—Med. Inspector. £E.720.

Swansea General and Eye Hospital.—H.S. £200.

Victoria Hospital for Children, Tite-street, Chelsea.—H.P. £100.

West London Hospital, Hammersmith-road, W.—H.P. and H.S. Each £100. Also Asst. Anesth. and Hon. Med. Radiologist.

Westminster Hospital, Broad Sanctuary, S.W.—Clin. Asst. and Refractionist to Ophth. Dept. £50.

Wigan Infirmary.—Third H.S. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments:—Hawes,

Yorks (North Riding): Wingate, Durham; Wednesbury,

Staffs; Chipping Campden, Glos.

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the

Newark and Nottingham County Courts. Applications

should reach the Private Secretary, Home Office, S.W.,

not later than June 23rd.

Births, Marriages, and Deaths.

BIRTHS.

MILNE.—On May 29th, the wife of Robert Milne, F.R.C.S., M.S., London Hospital, of a son.

DEATHS.

CLAPHAM.—On May 31st, at his residence, the Five Gables, Mayfield, Sussex, William Crochley Sampson Clapham, M.D., F.R.C.P.

KENNEDY.—On June 2nd, at King Henry's-road, Hampstead, Surgeon Captain Graham E. Kennedy, R.N.

TROUTBECK.—On June 3rd, at Ashley-gardens, S.W., suddenly, of angina pectoris, Henry Troutbeck, M.B., B.C.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

BRITISH HOSPITALS ASSOCIATION. SOME ADMINISTRATIVE PROBLEMS.

THE annual conference of the British Hospitals Association, held at Sheffield on May 31st and June 1st, was the opportunity for the statement and discussion of many intricate problems affecting the welfare and organisation of voluntary hospitals throughout the country. A section of Sir Napier Burnett's address on Voluntary Hospital Finance was abstracted in our columns last week. We select below from the communications made by Lord Hambleden on Hospital Finance in its Relation to Approved Societies, by Mr. H. J. Waring on the Future of Voluntary Hospitals from a Medical Viewpoint, and by Mr. H. L. Eason on Problems of Modern Hospital Administration, certain passages of especial importance.

HOSPITAL FINANCE IN ITS RELATION TO APPROVED SOCIETIES.

Lord Hambleden said that at the last annual meeting of the Association Mr. Thomas had fairly pointed out that the scheme of National Health Insurance, while it makes provision for the treatment of minor ailments which can be dealt with by the panel doctor in his surgery, makes no provision at all for the special treatment required for serious cases, which can only be dealt with in the hospitals of the country. However, though the grant which some of the approved societies had now agreed to make in respect of certain of their members who are treated as in-patients did not at present form more than a fraction of the sums received in payment by or on account of patients, in principle the payment was an important and welcome departure from the policy formerly followed by approved societies.

The governing bodies of the hospitals throughout the country had since the war been forced to look for an increase of income from payment by or on behalf of patients who receive treatment towards the cost of maintenance while in hospital. They were right in deciding that in respect of insured persons there was a double claim, for not only was the patient benefited in common with all others, but his society was saved considerable sums by the service which the hospital rendered in restoring him rapidly to health.

The societies, after many negotiations, decided in principle to allot a definite sum from realised surplus to the support of the hospitals, and it became necessary to devise means by which the amount available could be most equitably divided. Donations pure and simple were ruled out, for it was agreed that the scheme must be so drawn as to provide that every member might have a reasonable opportunity of participating, or, in other words, there must be some consideration to the societies for payment made. Throughout the negotiations it was the duty of those who represented the hospitals to agree to nothing which would encroach upon the principles of the voluntary system. There was, perhaps naturally, a tendency on the part of those who spoke for the approved societies to suggest that preference might be given to those of their members for whom payment was to be made. This question raised doubts in the minds of some hospital committees, but it was pointed out to the societies that hospital authorities acting through their medical staff must be the sole judges of the fitness for hospital treatment of all individuals who applied for it. The societies recognised the necessity of admitting this point and showed no desire to withdraw the grant in consequence of the decision of the British Hospitals Association representatives to make it a condition which could not under any circumstances be waived.

Amount of Payment by Approved Societies in 1922.

The basis of the scheme so far as the two great industrial societies were concerned is a payment in the first instance of £1 1s. per week in respect of each member entitled to additional benefits — i.e., those members who were insured not later than December, 1918, and were still members of the society on July 5th, 1920. The amounts set aside by the societies from which he had been able to obtain returns were as follows: the Prudential Approved Societies, £150,000 per annum; the National Amalgamated, £200,000 total to cover five years; the National Deposit Friendly Society, £75,000 total to cover five years; the Post Office Employees, £2000 per annum; the Sailors' and Firemen's Union, £400 per annum. Unfortunately the societies were not able to give their figures in a common form, some having made a return of the number of weeks' treatment paid for and others the number of persons for whom payment was made. The Prudential paid out in 1922 £83,000, or little more than half the amount of £150,000 set aside, for 45,000 weeks' treatment. The National Amalgamated paid out £42,138 for 24,072 weeks' treatment. The National Deposit Friendly

Society paid out £10,224 for the treatment of 2234 persons, or less than half the sum expected by them, as will be seen if we divide the total of £75,000 into five portions. The other two societies paid out less than £1000 between them. The total paid amounted to over £135,000, a sum by no means to be despised.

One interesting point in connexion with these payments is the fact that the amounts were much greater in the later than in the earlier quarters of the year. The Prudential, for instance, paid for 6567 weeks in the first quarter, 11,061 weeks in the second, 12,696 in the third, and 14,278 in the fourth. In the first quarter of this year 15,200 weeks are claimed for. The National Amalgamated returns 3800 weeks for the first quarter, 5585 for the second, 6542 for the third, and 8145 for the last. The National Deposit paid for 470 persons in the first quarter and 707 in the last: but in their case there was a curious drop to 443 in the third quarter. From these figures it would appear that hospitals were somewhat slow to avail themselves of the grant, for it did not seem probable that more insured persons were treated in the last than in the first quarter.

The balances which remained at the end of the year in the case of those societies which did not pay out as much as was expected were to be used as follows. The Prudential increased their payment from £1 to £2 per week after the first quarter of last year and carried forward their balance for distribution in this and succeeding years. The National Deposit Friendly Society stated that the experience of 1922 showed that if the payment had been fixed at 30s. per week instead of £1 1s. the amount available would have been approximately absorbed. The society had now agreed not only to increase the payment from £1 1s. to 30s. per week, but to make this apply as from the commencement of the arrangement. Steps are being taken to make the back payment, which will amount to nearly 50 per cent. of the £10,224 already distributed.

Figures Obtained from Hospitals.

Lord Hambleden had, moreover, received figures from more than 100 general hospitals of over 100 beds. From these returns it appeared that in London general hospitals insured persons were more than 20 per cent. of all in-patients, who numbered 97,761, but that only 9 per cent. of all patients were qualified for the additional benefit under the scheme. The variations in the figures were remarkable, for one hospital returned only 1 per cent., and another less than 1 per cent., although in the latter case all insured persons taken as in-patients numbered 17 per cent. of the whole. Lord Hambleden could hardly think that in this case and some other cases full advantage has been taken of the grant.

Some of the special hospitals showed a much higher average. A chest hospital had received grants for 30 per cent. of all its patients, but an ophthalmic hospital for 8 per cent. only, and an orthopaedic hospital for the same number. The amount received by the London hospitals from which he had received returns was £41,332, on account of 9915 patients.

The striking feature in the figures which he had obtained from provincial hospitals was the much higher percentage of insured persons treated by them. In the 35 hospitals in England which were able to give complete returns, of 108,000 patients 33,828 were insured persons, or over 31 per cent. Scotland showed a still higher average, for of the 34,000 patients of whom he had records 13,200 were insured, or 40 per cent. In England, outside London, the proportion of patients for whom some payment was made was 87 per cent. of all in-patients, and the total amount received was £57,498. In Scotland, although the number of insured patients was so high, the amount received was only given as £5200, of which £3820 was received by one hospital.

Lord Hambleden had no definite evidence to offer except of a negative kind as to whether the payment of this grant affected the growing system of workmen's contributions. Even if a contributor who was insured should make objection, it could well be pointed out that the donation made by the societies covered only a percentage of insured persons, and even for such persons represented but a fraction of the cost of maintenance while in hospital. While grateful for the undoubted help which this grant from the approved societies had brought to hospitals, Lord Hambleden mentioned two main criticisms. In the first place, the basis of the scheme was not one which made for permanency. The grant was made out of realised surplus, and its basis was precarious. In the second place, some societies might have surpluses, others might have none, and in the case of those fortunate enough to have balances to dispose of, their disposition depended upon the votes of their members. In the existing scheme societies representing only a little more than half the insured persons in the country were taking part: in the case of the remainder, when a surplus existed it was decided to use it for additional cash benefits.

A few years hence very important questions would thus necessarily arise. It would be a great mistake to give encouragement to the idea that those responsible for the

management of hospitals are prepared to surrender their principles for a cash payment. But the very fact that those principles are so strongly held and so widely supported should encourage them to preserve an open mind upon any scheme which can be proved to bring them nearer to a more perfect system of curing the sick and alleviating the troubles of the suffering.

Mr. H. J. Waring made some interesting suggestions on the GRADING OF HOSPITAL PATIENTS.

He pointed out that from a financial point of view patients treated in a hospital may be graded in the following classes:—

1. The necessitous poor who, from their pecuniary condition, are unable to pay or contribute anything. 2. The necessitous poor who can make a small contribution towards hospital accommodation and maintenance, but nothing for medical treatment. 3. The necessitous but not always poor who can pay the cost of hospital accommodation and maintenance, but nothing towards medical treatment. 4. The middle and professional classes, who can pay for ordinary hospital accommodation and maintenance and moderate fees for treatment. 5. The rich and upper classes, who can pay for better-class hospital accommodation and maintenance and ordinary fees for treatment. The requirements of these two latter grades (4 and 5) can be readily met by providing different classes of rooms. Thus for patients in grade 4 two- or four-bedded wards divided by partitions may be provided, or small single rooms of different sizes and aspects; and for patients in grade 5 larger rooms with a good aspect, or even a suite of rooms.

The practical result as regards the general institution of payment by patients for or towards hospital maintenance and treatment is, that in order to be fair to all classes of the community every voluntary hospital should provide suitable accommodation for all classes of the community who wish to avail themselves of its resources. In order to do this it will be necessary for most voluntary hospitals to build new accommodation suitable to this purpose.

The advantages which would be gained by the provision of accommodation for paying patients in a voluntary hospital would be as follows:—

To Patients.—Members of the upper, middle, and professional classes would be able readily to obtain institutional investigation and treatment of the same high standard as that which they provide or assist in providing for the necessitous poor.

To Hospitals.—(1) The special departments of many hospitals could be more fully and continuously utilised than at the present time, especially in hospitals where such departments are only open on two or three days or half days per week. Departments of pathology, X ray, electro-therapeutics and mechano-therapeutics are examples of this nature. (2) The overhead charges for general administration would not of necessity be increased, or in any case would not be proportionately increased; a portion of such charges could legitimately be transferred to the paying department, which could be made a source of profit to the hospital.

To Hospital Staffs.—Members of hospital staffs would be able to have some of their own patients in the private rooms or paying department, and thus save themselves considerable time in going from one private hospital or nursing home to another.

To Staff and Patients.—Resident medical officers could be appointed to a paying department of this kind, whose services would be available for patients in the absence of the patient's own medical man. The advantages provided by the establishment of a paying department of the kind mentioned would, I think, be most appreciated in connexion with maternity and surgery.

In the course of an address dealing with problems of hospital administration Mr. Herbert L. Eason, medical superintendent of Guy's Hospital, dwelt at some length on the

MAINTENANCE OF THE SUPPLY OF NURSES

on the basis that this is one of the most acute problems with which we are faced. According to him, the present supply of probationers is most precarious, and there are few hospitals that have a full nursing staff. Before the war probationers were not usually admitted for training until they were 23 years of age or over, but efforts to enlist the sympathy of head-mistresses in bringing nursing as a career to the notice of girls at school are met by the rejoinder that if there is a compulsory interval between leaving school and commencing training, the girl drifts off into some other occupation or career. Probationers are therefore admitted into many hospitals now at the age of 19, but the experiment is far from being a success. Girls of this age often do not know their own mind, and after a course of instruction in a preliminary training school many of them come to the conclusion that nursing does not appeal to them, or that it is too hard. The percentage of sickness among young nurses is also much higher than among older women, as they are not sufficiently resistant to disease. Of every batch of probationers entering

a preliminary training school at a hospital, from 25 to 50 per cent. may leave the hospital before the completion of their first year of training. It also appears to be the experience of many matrons that the more off-duty time that is allowed the higher is the incidence of sickness. The off-duty time is occupied with pleasure and amusement, and the nurse returns to her ward fatigued and more liable to infection. The probationer's life in these days is also made more strenuous by the increasing severity of her educational curriculum. The modern tendency is for the training of nurses to become more and more advanced on the scientific side, so that there appears to be a danger that the curriculum for probationers will be little less than that of the woman doctor. As most of this mental work has to be done by the nurse in her off-duty hours, when she is usually physically fatigued, the strain may soon become intolerable. As it is essential that a nurse should have a good physique, and physique and intellectual capacity do not always go hand in hand, there may be a danger that, in demanding too high an intellectual standard from our probationers, we shall lose those women who are by nature physically best fitted to undertake the strenuous life of the hospital nurse.

Nursing in the wards is also becoming harder and harder every day owing to the increasing demands of medical service. Investigations are becoming so complex, bismuth meals and special diets are adding so greatly to the routine work of a ward, and the number of persons who now have duties in the wards and require the attention of the nursing staff is increasing to such an extent that it is impossible to staff a hospital with the number of nurses that was adequate a few years ago. And the problem is not merely one of more nurses. More nurses require greater housing accommodation, greater nursing accommodation means an increased domestic staff, who in their turn require additional accommodation, and all the while the cost of maintenance in respect of food, heating, and lighting increases without limit. Then, again, at the end of the period of training, the fees now charged in private by the trained nurse are becoming so high that it is becoming increasingly difficult for persons of moderate means to afford their services, and nurses realise that there is hardly a living to be made.

The supply of nurses for hospitals, their training and the fees charged for their services in after life are, therefore, all problems which require the most cool-headed consideration on the part of those who are responsible for the future of the nursing profession. Finally, the pensions to which nurses can aspire at the end of their professional life are in most cases miserably inadequate, and a nurse is usually worn out at fifty. Her professional career is very short, and unless she is of a rigidly economical frame of mind the end of her life may be a sad struggle with actual poverty. It is essential, therefore, Mr. Eason said, in order to attract nurses of the right type in sufficient numbers to train at our hospitals that every attempt should be made to make their life, while in training, attractive by the provision of comfortable bedrooms, good sitting rooms, and amusement in the way of week-end cottages, sports grounds, nurses' leagues, and all forms of coöperative interest and social enjoyment. And for the trained nurse some adequate pension scheme is the problem of the hour.

FINAL PENSIONS AWARDS.

THE Minister of Pensions in a recent circular corrects a misunderstanding regarding certain decisions by the Pensions (Assessment) Appeal Tribunals on appeals against final awards. It is erroneously supposed that the setting aside of a final award by a tribunal implies that the award will be increased, or, if the appeal was against a nil disablement award or final weekly allowance, that a fresh award will be made at once. This is not the case. Under the War Pensions Act, 1921, the tribunal is empowered to confirm, increase, decrease, or set aside a final award, and its decisions are equally binding on the Ministry of Pensions and the appellant. The setting aside of a final award ordinarily means that the tribunal, without challenging the assessment, considers that the time has not yet come for the making of a final award. It does not necessarily follow that an increase in the current award will be due, or that a fresh award will be made if none is current. The man reverts to the position he was in before the final award was made. His case is then reconsidered under the Pension Warrants by the Ministry, and where necessary a further assessment by a medical board of his degree of disablement is obtained. In any event he has the right to claim re-examination on the ground that his condition has deteriorated. If the man's condition is found to have deteriorated, a fresh award is made; but if his condition has not deteriorated the current award remains in force. At a later stage, however, his case will again be considered with a view to a final award, and if the man is dissatisfied with such final award, he can avail himself of a further right of appeal to the Pensions (Assessment) Appeal Tribunal.

An Address

ON THE

DURATION OF PREGNANCY IN ITS MEDICO-LEGAL ASPECT.

Opening a Discussion at the Meeting of the Medico-Legal Society on April 17th, 1923,

By THOMAS WATTS EDEN, M.D.,

F.R.C.S. EDIN., F.R.C.P. LOND.,

OBSTETRIC PHYSICIAN, CHARING CROSS HOSPITAL, LONDON.

THIS contribution to the discussion of the duration of pregnancy in its medico-legal aspect proposes to state the difficulties in the way of estimating with precision either the normal duration of pregnancy, or in any given case, the stage to which it has advanced when the child is born. Our predecessors in obstetrics of a hundred years ago held definite and decided opinions upon the normal length of pregnancy in women, and they appeared to be very largely unaware of the difficulties with which the subject bristles. The famous legitimacy trial in the year 1816, known as the Gardner Peerage case, turned very largely upon the question of the extent to which it was possible for pregnancy to be prolonged in women. One of the medical witnesses, by name Sir Charles Clarke, laid it down that it was a law of nature that 40 weeks after conception was the latest period to which pregnancy could be prolonged. His feelings were so strong in the matter that, according to the custom of those days, he broke into Latin and declared that 40 weeks was "ultimum tempus pariendi mulieribus constitutum." We now know that to determine the normal duration of pregnancy is in reality a problem of great complexity, and, as we shall see, it probably does not admit of a precise solution.

The question is of medico-legal interest mainly in its bearing upon the question of legitimacy, and the problem usually presents itself thus: If a child is born upon a given date, can the date of its procreation be determined therefrom with precision? And if not, can limits be set beyond which the procreation of the child would not be possible? It is conceivable that in the future the question of parentage may be attacked in quite a different manner. I understand that it is the English law at the present time that points of physical resemblance do not constitute evidence which can be received in court. It is possible, however, that certain reactions of the blood may become of service under limited circumstances. The reaction of blood corpuscles in relation to clotting allows of four "blood-groups" being distinguished; it has been shown that these characters of the blood are transmitted on Mendelian principles, and it is not impossible that a given blood-group in the child may be shown to be incompatible with certain other blood-groups in the presumptive parents. In the meantime we are far from having arrived at this point, and the only possible medical contribution to problems of paternity lies in the question of the duration of pregnancy and its relation to the characteristics of the child when born.

PHYSIOLOGY OF MAMMALIAN REPRODUCTION.

The fundamental difficulty in determining the duration of pregnancy lies in the fact that it commences a profound obscurity. How can we state the duration of any phenomenon unless we can establish the time of its beginning as well of its ending? A further difficulty is that the termination of pregnancy in the birth of the child is frequently not its normal termination, and we have to speak of new-born infants as either premature, mature, or post-mature. It may be well, therefore, for me to begin by mentioning one or two salient points in the physiology of mammalian reproduction. The gestation process begins with the act of fertilisation—i.e., the union of the egg-cell (female) with the spermatozoön (male). The egg-cells

are in the ovary; periodically a certain number of them ripen, become liberated from the ovary, and enter the Fallopian tube in women, or the upper part of the double uterus in animals. The discharge of the egg-cells from the ovary is called the process of ovulation. In women ovulation is periodic, but its precise relation to menstruation is still undetermined; probably it occurs every three to four weeks in variable relation to the occurrence of menstruation. There are no outward signs by which the occurrence of ovulation in women can be recognised. As a rule only one egg-cell ripens at each ovulation; occasionally two or even three may ripen at the same time. Having reached the Fallopian tube the egg-cell has scant power of survival, and probably perishes in a day or two if not fertilised. Spermatozoa are deposited in the vagina in very large numbers, estimated at over 200 millions in each ejaculation. The greater number probably perish; a few make their way by their own motility into the Fallopian tube, and it is estimated that the journey from the vagina to the Fallopian tube takes about 24 hours. The vitality of the spermatozoa is remarkable, and they are able to remain active for very much longer than is the case with the egg-cells. As long ago as 1850 living spermatozoa had been found in the uterus from seven to eight days after insemination (von Haussmann). More recently a remarkable case was reported by Dührssen,¹ in which he found spermatozoa alive in the Fallopian tube 23 days after insemination. The case was that of a woman who was operated on nine days after her admission to hospital, and who stated that the last act of insemination had occurred 14 days previous to her entering the hospital. Even if the data in this case are not acceptable in their entirety, there is no doubt that in this instance the spermatozoa showed very remarkable powers of survival. In an unfavourable environment we know that spermatozoa lose their motility in a few hours; but in the plicated tubal mucosa they find conditions which are no doubt favourable, to a remarkable extent, to the maintenance of their vitality. We should not be justified in assuming, however, that the spermatozoa in all cases are able to survive as long as this.

In women the difficulty of determining the date of fertilisation is that although we can be reasonably sure that spermatozoa are in the genital tract, we never know when the egg-cell will be there to meet them. Further, the capacity of survival of the spermatozoa is probably variable in different individuals, and consequently an exact adjustment of insemination and ovulation may be necessary if pregnancy is to occur.

GESTATION IN LOWER MAMMALIAN ANIMALS.

In the case of lower mammalian animals the matter is somewhat simpler. In these creatures the approach of the male is only permitted at certain seasons of sexual activity; during the seasonal rut ovulation is very active, egg-cells are discharged in large numbers, and there is practical certainty that egg-cells and spermatozoa will meet with the minimum of delay. Hence, the fact that pregnancy almost invariably follows if the animals are healthy. Breeders of pedigree horses and cattle have given us some interesting figures of the duration of pregnancy in mares² and cows;³ in these cases coitus is limited to a single occasion, and is made the starting-point of the calculation. Their figures show that in cows the period of gestation varied from 252 days to 320 days; the mean of the extreme figures is 286 days, and the variation from the mean in either direction is about 12½ per cent. In mares the period of gestation varied from 311 to 394 days; the mean of the extreme figures is here 352 days, and the variation in either direction from the mean again amounts to about 12 per cent. The conclusion appears to be inevitable that in these animals the period of gestation is not fixed, but is actually variable within rather wide limits. As we have seen, there is a high degree of probability that fertilisation follows very closely upon insemination, and the margin of possible error is very narrow.

CALCULATION OF DURATION OF PREGNANCY IN WOMEN.

Turning now to pregnancy in women, there are two possible methods of calculating its onset: the date of intercourse and the date of the last menstrual period. The first method is seldom available, for unless the calculation can be made from a single act of intercourse it is not applicable. Carefully investigated instances have, however, from time to time been put on record, and a series of 40 were recorded many years ago by Reid.⁴ It is interesting to compare Reid's figures with those just quoted records of animals. The extreme limits were 260 and 294 days, the mean of these figures is 277, and the variation in either direction from the mean amounts to 6 per cent., or only one-half of that found in cows and mares. The degree of variation must further be subjected to some reduction on account of the high degree of probability that in many cases a considerable interval may have elapsed between insemination and fertilisation, for the reasons which have been already considered. It appears, therefore, that in women the normal duration of pregnancy, though variable, is not variable to the same extent as in cows and mares. No better illustration of variability can be quoted than the fact, which has frequently been observed, that two women in whom fruitful coitus occurred upon the same date may be confined at widely different dates (Lowenhardt).

The method of calculation from the date of the last monthly period naturally yields results which show much greater variation than those just mentioned. A series of 782 carefully observed cases are quoted by Simpson,⁵ in which the extreme limits were 252 days and 326 days. The mean of these two figures is 289, and the variation in either direction from the mean amounts to 13 per cent., a figure which closely approximates to that found in cows and mares. The margin of error in the calculation from the last menstruation is, however, so wide that we must now consider it in a little detail.

The first source of fallacy has been already mentioned—viz., the uncertainty as to the incidence of ovulation. It may occur in all probability at any part of the menstrual cycle, but clinical observations lead us to believe that the week immediately following the menstrual period is the time when it is most likely to occur. The menstrual cycle varies in length in different women, and may vary in the same woman at different times, and ovulation undoubtedly may occur at any point in the cycle. This fact probably accounts for the relative infrequency of fruitful coitus in women as compared with lower animals, and if it were not for the remarkable power of survival of human spermatozoa the odds against the occurrence of pregnancy would be much higher than is actually the case. We have seen that spermatozoa may remain alive in the Fallopian tube for three weeks, and it is possible that even that does not represent the extreme limit of their vitality. Once they have found their way to the tube, they can therefore await the arrival of the egg-cell, practically throughout the menstrual cycle, and in this way opportunities of fertilisation at any point of the menstrual cycle are clearly present. The uncertainty, however, remains, and it has to be admitted that fertilisation may occur as much as three weeks after the last monthly period even in the absence of a further coitus. The effect of such an error would be to make it appear that pregnancy has lasted three weeks longer than is actually the case.

This fallacy is fundamental, but there are two other fallacies which may be called accidental, and are only occasionally encountered. A small proportion of women habitually menstruate irregularly at prolonged intervals; in others menstruation may be suppressed for a time from illness, or nervous shock, or from the fact that they are nursing. Pregnancy may nevertheless occur under any of these conditions, and it is obvious that calculation from the last monthly period would then be greatly at fault. Occasionally the converse difficulty

is met with, for there are women who continue to menstruate for two to three months after conception has taken place. This occurrence is extremely rare; many alleged instances turn out on careful inquiry to be in reality attacks of bleeding due to minor pathological conditions and not to menstruation. The possibility of the occurrence cannot, however, be denied, and its effect will be to make it appear that pregnancy has lasted a shorter time than is actually the case.

AVERAGE DURATION.

It follows from what has now been said that nothing more than an approximate estimate can be made of the date of commencement of pregnancy in women. It is, therefore, necessary to fall back upon clinical observations in seeking a guide as to what is its normal or average duration. I think it would be preferable to speak of the average rather than the normal duration for wide variations from the average may occur without any clearly defined departure from the normal characters of the child when born. Such observations show that when the date of the last menstruation is taken 24 per cent. go to the fortieth week, 22 per cent. terminate in the thirty-ninth week, and 22 per cent. go to the forty-first week (Simpson). That is to say, 81 per cent., or four-fifths, terminate in the period of three weeks represented by the fortieth and the week earlier and the week later than this. The calculation can be made from coitus, 45 per cent. are found to terminate in the fortieth week, the total for the three weeks being 77 per cent., or very near the same as when the calculation is made from menstruation. The fortieth week includes the 274 to the 280th days, and in practice we are in the habit of reckoning 280 days from the cessation of the last period, or 274 days from the date of coitus.

Variations within the limits of three weeks may clearly be accounted for by the uncertain incidence of ovulation and are not incompatible with the assumption that the gestation process may actually be almost if not identically the same in 80 per cent. of cases. Much wider variations may, however, occur, and these can only be explained on the assumption that the actual process of gestation also varies in length; this may occur not only in different subjects, but in the same woman in successive pregnancies. The extreme limits in the series I have just quoted from Simpson were 252 and 326 days, an interval of 74 days, which clearly indicates variation in the length of gestation itself. Taussig⁶ quoted the case of a woman who in three successive pregnancies went 277 days, 325 days and 285 days respectively, which shows that a wide variation may occur in the same individual in the length of the gestation process.

If we accept the fact that the length of the gestation process in women is variable, it is not very easy to advance a satisfactory explanation of this variability because we do not know by what means pregnancy is terminated and the birth of the child brought about. What is it that brings about the expulsion of the child from the uterus? Many years ago I and others pointed out the fact that the placenta of a mature child showed degenerative changes which tended to render it unfit for the proper performance of its functions. These changes were due to age, for the placenta is an organ with a very brief life-cycle. It is possible that the progressive unfitness of the placenta for its work is the determining cause of the onset of labour, but what is the connecting link between placental degeneration and the outbreak of expulsive uterine action which leads to the expulsion of the child we do not know. Many interesting speculations might be made, but it would be unprofitable to touch upon them on this occasion.

FETAL MATURITY.

The point at which we have arrived is that we are quite unable to deduce with precision the date of procreation from the date of delivery. We must now inquire whether such a deduction can be made from the characters of the child when born. We know fairly

accurately the calculated period of pregnancy at which a child becomes viable—i.e., capable of a separate existence. The calculated period is 28 weeks, but as we have seen this may be an over-estimate up to the limit of about three weeks of the actual duration of gestation. We know, further, that the rearing of a child born between the calculated periods of 28 and 32 weeks is extremely difficult and the mortality among such infants is very high. There is very little difficulty in placing a premature baby in the calculated month to which it belongs, and when this point is of medico-legal importance the data are sufficiently accurate to allow of the expression of a decided opinion. It would be tedious to recite the dimensions of weight and length, and the other characteristics of prematurity, upon which reliance is placed, but I will here refer to an illustrative case from my own experience.

I was consulted several years ago upon a case in which the following were the pertinent facts. After a long absence the husband returned home on May 13th and lived with his wife for several weeks thereafter; the wife, who menstruated irregularly, had her last period on April 5th; the child was born on Nov. 23rd, 194 days after the date of the husband's return and presumably of the fruitful coitus. The doctor who attended the confinement expressed the opinion that the child was premature; it was weighed at 8 lb. at birth, but the scales were subsequently said to be inaccurate; it was nursed by the mother, and no trouble was found in rearing it. A child born at 194 days after fruitful coitus would be in the twenty-eighth week of gestation. The average weight of an infant born at that period is from 2½ to 3 lb.; it is extremely feeble and only very exceptionally can it be reared. I had no hesitation in expressing the opinion that a child born at 194 days could not possibly have weighed anything approaching 8 lb., its extreme prematurity would attract immediate attention to its condition, and it could not have been reared without elaborate care and precaution. The facts were inconsistent with such a degree of prematurity. In point of fact the case did not come into court, and I believe that the illegitimacy of the child was conceded.

In a popular medical work Shakespeare is quoted as asserting that a child may survive which comes into the world "full 14 weeks before the course of time." In our reckoning this would be the twenty-sixth week. The truth is that the medical work in question has totally misrepresented Shakespeare, and I should like to give the true account of what he did say about it. The passage occurs in *King John*, Act I. The younger son of the late Sir Robert Faulconbridge claims his father's title and estates on the ground that his elder brother is illegitimate. He pleads:—

"That this my mother's son was none of his (Sir Robert's);
And if he were, he came into the world
Full fourteen weeks before the course of time."

The elder son begs the truth of his mother on the ground that he himself bears no physical resemblance to his reputed father. He says:—

"We know his (Sir Robert's) handy-work:—therefore,
good mother,
To whom am I beholden for these limbs?
Sir Robert never help to make this leg."

And Lady Faulconbridge makes the confession:—

"King Richard Cœur-de-Lion was thy father:
By long and vehement suit I was seduc'd
To make room for him in my husband's bed."

He entirely disposes of the assertion that Shakespeare lent his authority to a statement in obstetrics so erroneous as that attributed to him.

In the case of lesser degrees of prematurity it is not possible to speak with precision, for the rate at which, after it is fully formed, the child increases in weight and in length is very variable. At term the average weight of the child is 7 lb. Whitridge Williams⁷ and in 500 carefully observed cases at calculated full term that the weight varied between 4 lb. 11 oz. and 6 lb. 12 oz. In a series of cases carefully estimated to be of 36 weeks development—i.e., a month premature—found the weight varied from 4 lb. to 7 lb. Similar

variations are found at all degrees of prematurity, and it must be admitted that the conditions which govern the weight of the developing child are largely unknown. The same is true of length, although this is, perhaps, a little more constant than weight.

Practically speaking it comes to this, that children born in the last four weeks of pregnancy may show all, or nearly all, the usual outward signs of maturity. Points of detail such as the proportion of nucleated to non-nucleated hæmocytes in the blood, and the ossification of the long bones, may in the future prove to be reliable guides to the stage of development, but at the moment our knowledge is incomplete, and does not allow us to make practical use of them.

PROTRACTED GESTATION.

Cases in which gestation exceeds the average duration are more often of medico-legal interest than those in which the average has not been attained. Cases in which pregnancy exceeds 300 calculated days from the last menstruation may be spoken of as cases of "protracted gestation." They are not very uncommon; probably something like 6 per cent. of cases surpass 300 days in Germany; in this country they are perhaps less common, and it is quite possible that racial characteristics have their bearing upon the length of the gestation process. It must be recollected that figures given in this connexion are calculated periods and are subject to the errors previously referred to. The extreme limit of calculated duration, at present on record, is, to the best of my knowledge, 336 days recorded by Bensinger.⁸ The calculation was made from the first day of menstruation and not from its cessation, which makes the period of gestation a few days longer than it would be if calculated by our method.

The calculated period in the Gaskill case was 331 days from the last coitus. Bensinger's case, which went to 336 days, was only 315 days from the last coitus, so that the Gaskill case actually surpassed all records based upon calculation from coitus. It is to be remembered, however, that the respondent alleged that a menstrual period had occurred in the month following her husband's departure, or it may have been the second month after, she was not sure which. If, therefore, the plaintiff was the father of the child, the case is in one respect unique, and confirmatory evidence would be absolutely necessary before it could be accepted as an authentic instance deserving of a place in medical records.

In what direction can confirmation be sought in such a case? Are there any confirmatory facts of medical value which would apply if available? There are, undoubtedly, such facts to be found in the characters of the child at birth, and to a less extent in the nature of the confinement. We have seen that the weight of the child born at term varies widely; I have myself recently delivered a woman at the 278th calculated day of a child which weighed 10½ lb., and I was satisfied that the child was not post-mature. My own opinion is that the possibility of post-maturity should be entertained in the case of all children weighing 10 lb. and upwards at birth. There are other foetal characters, besides weight which might very well be taken into account, but their consideration would be tedious, and perhaps too technical for this occasion. I propose, therefore, to consider the weight only in this connexion.

It would be of great assistance if we knew exactly what is the average rate at which the foetus in utero increases in weight during the last few weeks of pregnancy, or when pregnancy is prolonged beyond its usual limits. Unfortunately we do not know, but there is very good reason to believe that it is variable within rather wide limits. I have a record of all the cases which I have myself attended in private practice in which the calculated period lay between 290 and 300 days; the weight of the child varied from 8½ lb. at one extreme to 12 lb. at the other, the average being 9½ lb. In my memorandum on the Gaskill case I cited six cases accepted as authentic in which the calculated period lay between 320 and 336 days, and

I should like to give them now as follows. It is not claimed that this list is exhaustive; the cases are quoted as illustrative of their class.

Author.	Period.	Weight of child.
1. Rosenfeld* (1884) ..	311 days	12½ lb.
2. Sprenkel* (1895) ..	312 ..	12½ lb.
3. Sprenkel* (1895) ..	320 ..	11½ lb.
4. Taussig (1901) ..	323 ..	12½ lb.
5. Brosin* (1888) ..	324 ..	12½ lb.
6. Bensinger (1893) ..	336 ..	13½ lb.

* Quoted by von Winckel.¹⁰

These figures of weight are remarkably consistent in that all are at the least 65 per cent. above the average weight at term; and the highest weight, 13½ lb., is nearly double the average weight. At the same time the variations are well marked, and the weight is evidently not determined only by the duration of gestation.

SIZE AND MATURITY.

Medical authorities have always attached great importance to the large size of the child as evidence of post-maturity. Simpson⁵ and Matthews Duncan¹¹ both clearly expressed this view in their time, and it is unnecessary to labour the point. I must, however, refer to a recently recorded case which appears to be inconsistent with this view. Hendry,⁹ of Liverpool, has recorded a case of which the following are the salient facts. After a prolonged absence, the husband, a soldier on active service, returned to his wife for the night of May 14th to 15th, 1917, and then rejoined his unit. In June the woman had what is described as a "flooding"; the date she could not recollect. The child was born on April 8th, 328 days after coitus; the labour was easy, and was attended by a midwife who did not weigh the child at birth. It was weighed at a clinic on the seventeenth day after birth at 7½ lb. In my opinion the case must be rejected on account of the size of the child, for I cannot find a case on record where the calculated period exceeded 320 days in which the child weighed less than 12 lb. Confirmatory evidence of the mother's story is totally wanting, and the size of the child is not consistent with it. When the circumstances of the case offer inducements for misrepresentation the necessity for obtaining confirmatory evidence is obvious. And we must not overlook the fact that during the hard years of the war the curtailment of recreation and freedom by the Defence of the Realm Act led people widely to seek compensation in greater freedom of sexual relationship.

If we reject Hendry's case the evidence is consistent that children born after the 320th calculated day are so large that attention would be at once attracted to their size, and labour would, generally speaking, though not perhaps invariably, be difficult and tedious. Judged by these standards, the Gaskill case cannot for a moment be accepted as an authentic instance of protracted gestation. The child was not weighed at birth. The medical attendant in his examination in chief stated that the child was large and the labour difficult. After the appearance of the medical evidence, if my memory serves me rightly, he was recalled and deposed that the child was very large, and that it was the most difficult forceps case he had ever had. Bearing in mind the influence of suggestion upon our subconscious mental processes we may continue to regret that no immediate note was made of the weight of the child. The duration of gestation in the Gaskill case calculated from coitus was 331 days, and from analogy of other recorded cases of 320 days or over, the child should have weighed about 13 lb. The mother was a primipara—i.e., it was her first child—and there would inevitably be the greatest difficulty in delivering her of a child of that size, while its enormous bulk would have attracted the attention of the female population of the entire neighbourhood.

I submit, in conclusion, that sufficient medical data have been accumulated to show that human pregnancy may be prolonged to a period of 336 calculated days, and that there is nothing in the meantime to show that even this figure is the outside limit beyond which prolongation of pregnancy is impossible. Further,

I submit that cases of prolongation of pregnancy beyond 320 calculated days are so rare that alleged instances should be very carefully scrutinised, and that confirmatory evidence should be forthcoming if they are to be accepted as authentic. The child would in all cases be much above the average weight of children born at term; moreover, the other bodily dimensions of the child, which have not been referred to in the paper, would be also much above the average. If such confirmatory evidence is wanting, and if the circumstances of the case offer inducements for misrepresentation, we as doctors would be obliged to reject the authenticity of the case. I hope this will not be understood as questioning the justice of the decision in the Gaskill case. I realise, of course, that that decision meant that the plaintiff had failed to establish his contention, and not that the defendant had succeeded in establishing hers.

UNHEALTHY TONSILS ASSOCIATED WITH CERVICAL ADENITIS.

BY WALTER G. HOWARTH, M.A., M.B. CAMB.
F.R.C.S. ENG.,

SURGEON TO THE THROAT AND NOSE DEPARTMENT, ST. THOMAS'S HOSPITAL; LARYNGOLOGIST TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK;

AND

S. ROODHOUSE GLOYNE, M.D. LEEDS,
D.P.H. LOND.,

PATHOLOGIST TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

(From the Pathological Department, Victoria Park Hospital.)

SOME two years ago we published a short paper¹ on this question with a view to exploring the relationship which appears to exist between chronic enlargement of the palatine tonsils and cervical adenitis. The conclusions we arrived at were that cervical adenitis is frequently due to chronic septic absorption from the tonsils, that in addition, some 5 per cent. of enucleated tonsils show signs of infection by the tubercle bacilli and that this latter infection probably takes place in a tonsil already heavily charged with other pathogenic and saprophytic organisms. The present investigation was undertaken, therefore, in order to obtain, if possible, more definite experimental proof of the march of events than at present exists. The series of tonsils was obtained from the laryngologic department of St. Thomas's and Victoria Park Hospitals, and the operations were done by one of us (W. G. H.) by the method of enucleation described some years ago.² Well-marked cervical adenitis was present in all the cases.

Anatomy and Histology of the Tonsil.

The main histological features of the normal tonsil—if such a thing exists after the first few days of life (Davis³)—are well recognised and have been described in detail from the developmental and anatomical points of view by Barnes⁴ and others. From the present point of view the most important features of the histological picture are as follows: The fibrous capsule, the trabeculae of connective tissue, the covering of stratified squamous epithelium, the

crypts, the lymphoid tissue, the vascular supply, the lymphatics, and the mucous glands of the pharyngeal mucosa. In the careful description of the tonsil given by Barnes the author emphasises the fact that the tonsil lies in and not under the pharyngeal mucous membrane, and that it is in reality simply a complicated mucous membrane with lymphoid nodules developed in the more superficial fibres of its tunica propria. This point is probably important. The fact that the tonsil is thus separated from the surrounding tissues may explain why a chronic septic infection of the organ can remain so localised.

Before leaving this subject two points appear to us to need special emphasis, the crypts and the lymphatics. The crypts extend through the whole substance of the tonsil as far as the capsule; they are frequently branched and often open obliquely on to the free surface of the tonsil. They almost invariably contain debris of one sort or another, and are thus a very potent source of infection. The lymphatic vessels of the tonsil are still under discussion. Barnes states that no afferent lymphatic vessels have yet been demonstrated leading to the tonsils, though there are records of experiments (Lénart⁵ and Henke⁶) which show that colouring matter injected into the mucosa of the turbinate bones, and of the gums, may appear in the tonsil. The efferent lymphatics of the tonsil pass through the fibrous trabeculae and the capsule, and there unite into three to five trunks which pierce the buccopharyngeal fascia to go to the deep cervical glands, along with similar vessels from the base of the tongue.

For the purposes of our inquiry it has seemed advisable to investigate the morbid histology and the bacteriology separately.

Morbid Histology.

In the first place a series of 34 enlarged tonsils from cases with marked cervical adenitis were examined histologically. The following tissue changes were observed.

1. *Increase of Lymphoid Tissue.*—This was the commonest lesion noted. Some discussion has taken place as to whether or no this can be regarded as a true pathological change. In view of the fact that bacteria were found in some portion of the tonsil in every case examined, and that increase of lymphoid tissue in other parts of the lymphatic system is a direct reaction to infection, there seems to be little reason to doubt that the so-called hyperplasia of the lymphoid tissue of the tonsil is a pathological condition.

2. *Desquamation of Stratified Epithelium.*—This was commonly seen both on the free surface of the tonsil and in the crypts, and was generally found at points where invasion of bacteria had taken place.

3. *Cellular Infiltration.*—This occurred round small clusters of bacteria in various parts of the tonsil, notably in and beneath crypt epithelium, in connective tissue trabeculae, and free in the lumina of crypts. The cells concerned were lymph corpuscles and epithelioid cells. This cellular infiltration was, of course, not so extensive as it is in an acute follicular tonsillitis.

4. *Plugging of the Orifices of Crypts.*—Usually with cellular debris, mucus, and small masses of bacteria. Occasionally crypts become dilated so that they form cyst-like spaces lined with stratified epithelium, and may contain fibrin, lymphocytes, and stratified epithelium. At first sight these dilated crypts, when completely filled with degenerated cells and debris, superficially resemble patches of caseation. In one tonsil of our first series,¹ where there were giant cells near the crypt, this resemblance was striking.

5. *Increase of Connective Tissue in the Trabeculae.*—In these cases fibroblasts were numerous and the blood capillaries stood out clearly with connective tissue round them. These connective tissue changes were, however, not common.

Bacteriological Examination.

This series of tonsils was also examined for bacteria by the usual way of staining by Gram's method. Organisms were found in one portion or another of

every tonsil thus examined. Sometimes they were discretely arranged, at others they were in more or less solid masses. The bacteria were found in the following situations:—

1. On the free surface of the tonsil, and penetrating the stratified squamous epithelium. (Fig. 1.)
2. Together with mucus and degenerated cells plugging the orifices of crypts.
3. Lying free in the channel of the crypts. (Fig. 5.)
4. Penetrating crypt epithelium. (Fig. 5.)
5. Lying in the diffuse lymphoid tissue immediately beneath the crypt epithelium.
6. In the connective tissue trabeculae, generally within perivascular lymph vessels. (Fig. 3.)
7. In connective tissue between the bundles of muscle fibres of the palato-glossus and palato-pharyngeus muscles—i.e., outside the capsule of the tonsil. (Fig. 4.)
8. In one section lying within mucous glands.

It was noted that the bacteria, although frequently present in the diffuse lymphoid tissue lying immediately subjacent to the crypt epithelium, were not found in the lymph-nodes proper. Presumably if bacteria were carried there they were rapidly destroyed. Bacteria on reaching the tonsil appear to follow a definite path—viz., through the stratified epithelium (generally crypt epithelium), into the diffuse lymphoid tissue immediately beneath, and thence along the minute lymph channels of the trabeculae to the capsule, where they pass into the larger lymph vessels of the pharyngeal wall which go to the deep cervical glands.

Classification of the bacteria by means of their morphological appearance seen in sections was not possible. The organisms were roughly grouped as follows:—

	Cases.	Cases containing streptococci.
Cocci only	22	3
Bacilli and cocci	10	1
Actinomyces-like granules	1	—
Actinomyces-like granules and bacilli	1	—

The two cases showing actinomyces-like granules need separate description. The first was from a girl, aged 15, with pulmonary and abdominal tuberculosis, and the second was from a boy of the same age, both cases having discrete palpable glands. In the second case there were minute abscesses in the tonsil from which a mixed flora was cultivated (haemolytic and non-haemolytic streptococci, *Staphylococcus albus* and *aureus*, and *M. catarrhalis*). No granules were noted with the naked eye in either case, but in stained sections they appeared as darkly stained points about the size of a pin's head. In all the sections examined the fungus was seen to lie free in the lumen of the crypt, with a few leucocytes and desquamated epithelial cells around. No invasion of tonsillar tissue was noted, and no giant cells were seen. The fungus showed a tangled mass of filaments with cocci intermingled with them. At the periphery enlarged free ends of the filaments resembling actinomyces clubs were seen. All the elements stained well by Gram's method, but were not acid-fast.

These actinomyces-like fungi have been described by numerous writers, and the whole subject has been reviewed by Davis⁷ to whose paper we are indebted for a careful description of the parasite. He considers that the fungus is not a true actinomyces, but consists of a mass of fusiform bacilli, cocci, and spirilla in symbiosis, and finds that the fungus does not produce a true actinomyces culture on artificial media. The enlarged ends of the filaments which resemble true clubs are really central filaments with large numbers of bacilli clustered around, and Davis aptly likens this appearance to the bristles of a test-tube brush. He seems to imply that there may be some relationship between the elements of this actinomyces-like granule and the organisms of Vincent's angina. Unfortunately our two specimens were met with more or less accidentally in a series of tonsils devoted to histological study and therefore no cultures of the fungus were made, but the appearances in sections agree with Davis's description.

FIG. 1.

Masses of cocci in surface epithelium of tonsil ($\times 400$).

FIG. 2.

Actinomyces-like granule in lumen of crypt ($\times 20$).

No histological signs of tuberculosis were seen in this series of 34 tonsils, and only one case (one of the actinomyces patients) gave a clinical history of tuberculosis. It was interesting, therefore, to compare the findings with those recorded in our first published series of 100 cases examined solely from the point of view of tuberculosis. In this latter series five cases of tuberculosis of the tonsil were recorded out of the 100. Although a giant cell was very occasionally found in the surface epithelium or in the crypt epithelium, the majority of the giant cells seen in a large number of sections from these five positive cases were in the lymphoid tissue. (Fig. 6.) Sometimes these cells were found in the middle of a lymph-node, sometimes in the deeper part of the lymphoid tissue near the capsule, or alongside a trabecula, but, generally

speaking, they were in the diffuse lymphoid tissue subjacent to the crypt epithelium. It would seem, therefore, that the tubercle bacillus has a special affinity for the lymphoid tissue of the tonsil, as it has for lymphoid tissue elsewhere, and is rarely found in any other part of the organ; whereas pyogenic organisms are to be found in almost all parts of the tonsil except in the lymph-nodes proper.

Further Bacteriological Examination.

As it was impossible to classify the organisms from the morphological appearances in sections, two new series were examined. In the one all organisms cultivated, whether saprophytic or pathogenic, were examined, in the other virulence tests were made direct from the tonsils. In the first of these two series, agar and blood-agar plates, serum slopes, and broth-tubes were planted with secretion from (a) the crypts and (b) the cut surfaces of the bisected tonsil. The organisms found were as follows:—

Streptococcus	{ Haemolytic .. 16 }	..	38
	{ Non-haemolytic 22 }	..	..
<i>M. catarrhalis</i>	..	..	21
<i>Staphylococcus</i>	{ albus .. 8 }	..	19
	{ aureus .. 11 }	..	..
<i>Pneumococcus</i>	..	..	13
Unidentified bacteria	..	..	12
<i>B. influenzae</i>	..	..	7
<i>B. hoffmanni</i> and diphtheroids	..	..	5
<i>B. diphtheriae</i>	{ Virulent to guinea-pig 1 }	..	2
	{ Non-virulent .. 1 }	..	..
<i>Spirochaeta vincenti</i> and <i>B. fusiformis</i>	..	..	2
<i>B. coli</i>	..	..	1
Total	..	..	120

In almost every case the same bacterial flora was found in the crypts as on the cut surfaces. The two specimens of Vincent's angina were diagnosed on film preparations from minute abscesses opened up when the tonsil was bisected. It may be noted in passing that these minute abscesses are not uncommon. The organisms found in them in our different series varied—twice the organism of Vincent's angina, once actinomyces-like granules, and on other occasions a mixed flora including streptococci. In no case did an abscess contain tubercle bacilli. These small abscesses are doubtless caused by the plugging of the orifices of crypts and retention of infected debris.

Deducting the two organisms of Vincent's angina, which were not cultivated, 118 strains of bacteria were obtained from 33 tonsils, making an average of three strains for each tonsil. No single tonsil was found to be sterile, whilst the highest number of strains found in one tonsil was seven. The published records of other observers⁸ show a correspondingly wide range of bacterial species.

FIG. 3.

Cocci in perivascular lymphatics of connective tissue trabeculae ($\times 400$).

In the next series of 32 cases the tonsils were examined for pathogenic organisms only. Each tonsil was cut up into minute pieces with sterile scissors and an emulsion of tonsillar tissue made in saline solution. Half a cubic centimetre of this emulsion was then injected intraperitoneally into the mouse. In 14 cases (44 per cent.) there was no pathogenic effect, whilst in 18 (56 per cent.) the mouse died in 24-48 hours. From these latter cases 21 strains of bacteria were isolated from the peritoneal exudate. These organisms were as follows:—

Streptococcus	{ Haemolytic .. 8 }	..	..	15
	{ Non-haemolytic 7 }			
Pneumococcus	{ Type I. ... 3 }	..	..	6
	{ Type IV. ... 3 }			
Total	..	..	..	21

These pneumococci were all bile soluble. The agglutinating sera for typing were supplied by the Wellcome Research Laboratories.

On the clinical side it was noted that in the 14 cases in which no pathogenic organisms were found in mice, the enlarged cervical glands were of the discrete variety; whereas in the 18 cases whose tonsillar emulsions proved fatal to mice five cases had greatly enlarged masses of glands, of which one case had recently had an attack of acute adenitis. Three of these five cases yielded non-haemolytic streptococci in the peritoneal exudate of mice, one a haemolytic streptococcus, and one a Type I. pneumococcus.

Finally, two other bacteriological questions were very briefly investigated—viz., (a) the presence of anaerobic organisms in tonsils and (b) the relative toxicity of the haemolytic streptococci. Plate cultures from the crypts and cut surfaces of eight tonsils were incubated anaerobically in a Bulloch's apparatus and showed no growth. Nine strains of haemolytic streptococci were injected intraperitoneally into mice, using graduated doses of 1, 1/2, 1/5, and 1/10 of an agar slope. Of these nine strains four killed in all doses, and two in all but the lowest dose, whilst the remaining three were only virulent in a full dose of one agar slope.

Summary of Results.

1. In the enlarged and unhealthy tonsils associated with cervical adenitis in children the chief histological changes noted were (a) marked increase in the lymphoid tissue, and (b) lesions in the crypts—desquamation of epithelial lining, plugging of the orifices, dilatation of lumen into cyst-like spaces, and occasionally the formation of minute abscesses.

2. Every tonsil examined showed evidence of bacterial infection. Many different species of organisms were found, the maximum number of species found in one tonsil being seven, the average number three. The streptococcus was the commonest species noted.

3. In a series of tonsils examined for the presence of pathogenic organisms, it was found that 56 per cent. possessed bacteria virulent for the mouse. These organisms were haemolytic and non-haemolytic strepto-

Giant cells in lymphoid tissue ($\times 45$).

NOTE.—The drawings were made by one of us (S. R. G.) with the aid of camera lucida. In the case of the sections showing bacteria, they were made with 1/16" Leitz oil-immersion lens and then reduced to present size in the process of printing.

cocci, and pneumococci (Types I. and IV.). This pathogenic group of cases showed greater liability to the development of large masses of cervical glands (five out of 18) than did those cases of the non-pathogenic group (none out of 14).

4. The hæmolytic streptococci varied as to their virulence in the mouse.

5. Bacteria demonstrated in sections (chiefly cocci) showed that the infection tended to follow a definite path—viz., through the stratified epithelium (generally in the crypts, where it is thinner than on the surface) into the diffuse lymphoid tissue, thence along the minute lymphatics of the connective tissue trabeculae to the capsule, whence they passed to the lymph tracts of the pharyngeal wall.

6. In a separate series examined for tuberculosis it was found that the giant cells were generally in the lymphoid tissue, being rarely seen elsewhere.

7. In two cases actinomyces-like organisms were obtained, but there is reason to believe that they were not true ray fungi.

Conclusions.

It is said that the tonsils become infected with bacteria in the first few days after birth (Davis²); certainly in all our cases—children ranging from 2 to 15 years of age—infection was present, the line of march of the infection being illustrated in the drawings. In our series rather more than half of the children with enlarged and unhealthy tonsils associated with cervical adenitis harboured pathogenic organisms in their tonsils, the streptococcus being the commonest organism. On the other hand, tuberculosis was only found in about 5 per cent. of cases.¹

It seems probable, therefore, that tuberculosis is only a late infection, and that in the majority of cases the cervical adenitis is due to septic absorption from tonsils containing pyogenic organisms such as the streptococcus. This view is borne out by the fact that when the infected tonsils are removed by operation the affected glands frequently subside.

We are indebted to Mr. A. W. Smart, chief laboratory assistant, for help with this work, the expenses of which were defrayed by a grant from the Medical Research Council.

THE ÆTIOLOGY OF INDIRECT INGUINAL HERNIA.

BY T. E. HAMMOND, F.R.C.S. ENG.,

ASSISTANT TO SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF.

BEFORE any of the internal viscera can be protruded through the abdominal wall, there must be an increase of intra-abdominal pressure together with a weak spot in the wall itself. The inguinal region is a favourite site for the development of hernia, which is sometimes attributed to the weakness caused by the passage of the cord through the abdominal muscles, but this is more apparent than real.

Theories of Causation.

Of the numerous theories put forward to account for the formation of inguinal hernia, those based upon some abnormal intra-abdominal condition or some unusual weakness of the inguinal region are generally applicable, since hernia is as common among the

well-developed as the poorly-developed, and is associated with no particular type of abdomen. The congenital saccular theory of Mr. Hamilton Russell, based upon anatomical and pathological findings and supported by the result of excision of the sac, is to-day accepted by most surgeons. Some, however, declare that by this theory no explanation is forthcoming for the delay in the development until puberty or later, and that, following the sudden descent of the bowel into such a sac, some symptoms of strangulation with bruising and tenderness would certainly be present. Consequently, though it might account for the acute and subacute forms, no explanation could be put forward for the so-called symptomless form, where a reducible hernia arises often after some trivial accident, the only symptom being a feeling of something giving way or a fleeting pain. Considerable divergence of opinion has existed in the past over the possibility of this symptomless form, and many have contended that such an onset is impossible and that the accident has served merely to draw attention to a previously existing hernia.

For some years the writer has given special attention to the history of hernia cases, and has come to the conclusion that a symptomless onset is not uncommon at any age. In children the sudden descent of the bowel into the scrotum without strangulation or bruising is often seen. During the recent war such an onset was frequent, and many of the men were of good development. In some it occurred soon after enlistment, in others only after service abroad, the apparent cause being a slip at drill or a stumble in the trenches. As the hernial regions were carefully examined at the medical inspections, the probability of a gradual onset can be excluded. Two men of the battalion to which I was attached in Gallipoli developed hernia shortly after a medical inspection held by me. In each there was a slip while carrying a load; there was no nausea or vomiting, and the hernia, which was not tender, could be easily reduced. Such a history is not uncommon in civilian practice when no question of compensation arises, and seems absurd that it should always be discredited because at times a hernia is wrongly attributed to an accident. It is surely more in keeping with scientific principles to face facts and to endeavour to find some explanation, rather than to dismiss them as resulting from inaccurate observation.

Anatomy of the Inguinal Region.

The absence of marked symptoms and a delayed onset are quite consistent with the saccular theory, and it is mainly with this aspect of hernia that this paper deals; but before proceeding to study the mechanism of hernia, some points in the anatomy of the inguinal region and in the relation of the abdominal wall to intra-abdominal pressure will first be noted.

The Inguinal Canal.—This is a potential space normally filled by the spermatic cord, and, as the internal and external rings are not exactly opposite it has a valvular arrangement. The walls are not adherent to one another or to the coverings of the cord. The fascia transversalis, which is prolonged over the cord at the internal ring, has here a funnel-like appearance, and its margin is not sharply defined. Immediately above and in front lie the curved muscular fibres of the internal oblique and transversalis, which on contracting become opposed to Poupart's ligament and act as a sphincter to control the internal ring, compression of the spermatic vessels being prevented by the downward convexity of Poupart's ligament. That this is the action of the muscle can be shown by allowing the patient to cough or by electrical stimulation of the nerve when the canal is exposed during herniotomy; that it is intermittent is indicated by the muscularity of the fibres.

The contents of the cord are bound together by lamellæ of areolar tissue, the coverings are loose, and the spermatic vessels are tortuous and branch obliquely. In the foetus the processus vaginalis is present, but normally it should become obliterated soon after birth. Occasionally it remains patent throughout life, an

may retain its connexion with the tunica vaginalis or be obliterated at any point between this and the internal ring. Mr. R. W. Murray has shown that in such cases the bowel may never enter the sac. In anatomical and pathological dissections such sacs are narrow and are compressed by the surrounding tissues, but such an appearance is due to secondary hardening of the tissues and is not an accurate picture of the condition present in the living. When they are found during operations for varicocele, &c., with no history or signs of hernia, the finger can be passed, without meeting any serious resistance, into the peritoneal cavity. Such a sac lying among structures loosely bound together does not penetrate the belly of any muscle, but lies in the intermuscular plane, an important point in the symptomatology, since intermuscular tension, unless severe, rarely gives rise to pain.

Relation of the Abdominal Wall to Intra-Abdominal Pressure.—There is normally room in the peritoneal cavity for all the viscera. The slight pressure upon the walls due to gravity may be raised by the descent of the diaphragm or by the contraction of the abdominal muscles. At such times the protrusion of the viscera is prevented by the resistance of the peritoneum and fascia, supported when necessary by the action of the overlying muscles. When the diaphragm descends, the canal is protected by its valvular arrangement, and by the action of the inguinal sphincter when the abdominal muscles contract. With inspiration, the pressure, which is at first directed downwards and then downwards and outwards, closes the canal from within outwards. As the force of compression of the posterior against the anterior wall of the canal is always equal to the pressure upon the internal ring, there will be no tendency for the viscera to protrude.

The Mechanism of Hernia.

In the first place, the inguinal sphincter being a part of the abdominal musculature, its contraction is synchronous with theirs; and, as the rise of pressure is secondary to the action of these muscles, it is obvious that the internal ring is protected by the contraction of the sphincter before any strain is put upon it. The development of the sphincter being proportionate to that of the abdominal muscles, and the rise of pressure dependent upon the force of their contraction, any muscular effort which endangers the canal will be resisted by a force in direct proportion to the effort expended. It is, however, possible that during some severe or prolonged strain the sphincter may be overcome and the internal ring exposed to the pressure above.

The carrying out without injury of great ranges of movement, which is well seen in the spine with its complicated arrangement of ligaments and joints, is made possible by a perfect involuntary muscular coördination; as a result there is a defensive contraction of the muscles when any strain is placed upon the underlying ligaments. Yet a slight slip may cause a severe sprain, owing to the suddenness of the movement leading to incoördination of the muscles and to the consequent excessive stretching of the ligaments. Now the strength of the inguinal canal is largely dependent upon the action of the neighbouring muscles, which may become incoördinated here as elsewhere. For instance, when a weight is lifted from the ground, the legs are firmly fixed, the abdominal muscles contract, and the internal ring is protected by the sphincter. The giving way of either leg might lead to incoördination of the muscles, and consequently to relaxation or irregular contraction of the sphincter at a time when the abdominal pressure is raised.

The internal ring will be exposed to pressure from above, only if the latter is sufficiently severe to overcome the sphincter, or if some incoördinated action of the inguinal muscles takes place. Such an exposure is only momentary, and normally would not be followed by protrusion of the viscera, since sudden stretching of the peritoneum is unlikely. But with a persistent patent funicular process present, the bowel might enter the sac provided it was at the

time situated over the orifice. The point at which it would be arrested would be the apex of the sac, though possibly at the external ring if it were small; the loosely bound structures surrounding the sac would offer little resistance to its descent.

Symptoms of Onset.—The introduction of the finger into the inguinal canal gives rise to little discomfort, and, as bowel and omentum are freely movable in the abdominal cavity, their passage into the canal cannot in itself give rise to pain or other symptoms. These could arise only from interference with their function, from some alteration in the surrounding structures such as distension of the sac and stretching of the muscles or fascia, or from tearing of the tissues. Both bowel and omentum are insensitive to pressure unless it is sufficiently severe to interfere with their function or nutrition when symptoms of strangulation are present. Traction upon the mesentery may lead to faintness and nausea.

The funicular process is homologous with the peritoneum and tunica vaginalis, and probably possesses similar sensitiveness. Though dragging upon or nipping of these structures gives rise to pain, distension such as is seen in large hydroceles or in marked ascites causes little discomfort. When the bowel enters the sac it is in contact with a surface similar in every respect to that lining the abdominal cavity, no inflammation is set up, and pain is present only if the distension is sufficient to produce dragging upon the parietal peritoneum. Of the surrounding structures, the coverings of the cord are loose, and the fibres run longitudinally; stretching would be counteracted by a pulling upwards of the testis. The only place where tension is likely to arise is at the aperture in the fascia transversalis; but this, if small, will constrict the bowel and cause strangulation. The vessels are tortuous and the branches, which are given off obliquely, are not ruptured, and there will be no hæmorrhage.

From the above points, based upon anatomical and pathological considerations, it is seen that, as the inguinal canal is very efficiently protected from pressure acting from within the abdomen, the presence of a persistent patent funicular process does not signify that a hernia must necessarily form. This would take place only if the internal ring were exposed at a time when the intra-abdominal pressure was raised, which might follow some severe effort or a trivial accident leading to incoördination of the neighbouring muscles. Bruising is not to be expected, and the severity of the symptoms will depend upon the size of the aperture in the fascia transversalis; this, if small leads to strangulation of the bowel, but if large the only symptoms present might be a feeling of something giving way or a passing pain. An onset, symptomless and perhaps delayed until puberty or later, is therefore not inconsistent with the saccular theory, by which alone can other points in the ætiology of hernia be explained. The question is too large to be discussed in this paper, and I shall choose one that has been of much interest to me—namely, the possibility of the cure of hernia by the wearing of a truss.

Possibility of Cure by Truss.

Hernia other than in infants can be cured only by removal of the sac. As this has been present from birth, and as the exciting cause of hernia is some temporary incoördination of the inguinal muscles, it might be assumed that, following its immediate reduction, control over the canal would be regained. This is not the case, for recurrence of the hernia is certain, though it may be delayed for a few months. The reason is that before the descent of the bowel the orifice of the sac was on a level with the surrounding peritoneum, and the sides were in contact partly from a natural tendency to adhere, partly from the support of the neighbouring tissues. Once the hernia has formed, the orifice gapes and becomes shelved towards the canal, which is further weakened by the temporary paresis of the sphincter that follows its stretching; and a condition favourable to the descent of the bowel is now present. Up to the age of 2 the wearing of a

truss may lead to a cure if the hernia is kept continuously reduced, due in all probability to the tendency for the funicular process to undergo its normal evolution at this period. Often such a cure is only apparent and the hernia recurs later in life. In children an apparent cure is sometimes seen, in adults it is rare. This can be explained by the fact that in babies a rubber truss is quite efficient; the pressure it exerts is very slight, and with the tendency for the tissues to undergo their normal development, a condition of the inguinal region arises similar to that seen in a child where the cord contains a congenital sac into which the bowel has never descended. In children and adults a spring truss must be worn, the constant pressure of which leads to atrophy of the underlying muscles, as a result of which the sphincter will never be sufficiently strong to resist any great pressure from above, and the control over the canal will always be imperfect.

Operation and Recurrence.

The strength of the inguinal region depends upon the normal development and an unimpaired action of the neighbouring muscles. As in hernia there is no primary weakness, a permanent cure should follow the removal of the sac. Recurrences, however, are not infrequent, and the large number of operations which have been described bear witness to this. They are, in my opinion, due to want of attention to the development of the inguinal muscles, to failure to suture the incision in the fascia, or to the abuse of trusses.

The wearing of a truss, except in babies, is a purely palliative procedure, and by causing atrophy of the muscles may do much harm. After the age of 2 an operation should be performed as soon as possible; if its postponement is necessary, a truss with only a light spring will do the least harm. During the operation the incision in the internal spermatic fascia may be prolonged into the fascia transversalis. At the aperture so formed the peritoneum comes in contact with the external oblique and may become adherent to it. When the abdominal pressure is raised by the descent of the diaphragm the resistance of the fascia is wanting at this spot; and when raised by contraction of the abdominal muscles, the adhesions may interfere with the action of the sphincter. The incision in the fascia should always be carefully sutured, leaving just sufficient room for the passage of the cord. Following the operation it is essential that the muscles should be brought fully and powerfully into play immediately any strain is thrown upon the inguinal region. Voluntary exercises and electrical stimulation should be instituted to overcome the pre-operative wasting, which will certainly be present if the hernia has existed for some time, or if a truss has been worn, and also to prevent the post-operative wasting which follows disuse and the formation of adhesions. In the operation recommended by Mr. Philip Turner the incision in the external oblique is not prolonged into the external ring, and the early contraction of the external oblique will do no harm since the pull will be in the line of and not across the incision. After the operation for inguinal hernia voluntary exercises should be commenced on the fifth day and the patient should be up on the seventh, unless some plastic operation to overcome any secondary weakness has been performed, when a longer convalescence is advisable.

THE LATE DR. JOHN PENN MILTON.—The death occurred on May 21st of Dr. John Penn Milton, who since the opening of the East Sussex County Council Sanatorium at Darvell, Robertsbridge, in May, 1921, had been medical superintendent. He was 51 years of age, and he died from disease contracted during the war, in which he served on several fronts. He was a son of Mr. J. P. Milton, a Penzance solicitor, and in his young days was champion swimmer of the West of England and golf champion of Cornwall and Devon. Studying medicine at King's College Hospital he became M.R.C.S. and L.R.C.P. in 1898, and was appointed medical superintendent of the sanatorium at Hawkwood, and tuberculosis officer under the Devon county council. He was a recognised authority on tuberculosis.

A NOTE ON DRUG THERAPY IN DISSEMINATED SCLEROSIS.

BY W. JOHNSON, M.C., M.D. LOND.,

ASSISTANT PHYSICIAN, ROYAL SOUTHERN HOSPITAL, LIVERPOOL,
AND TO THE ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

ALL those who have watched the course of this malady will not be inclined to disagree with the statement that it stands as almost the most tragic of all diseases. In the first place, it affects the individual in the early prime of his life. Its commencement is often trivial, and the first attack of the disease is commonly regarded as "influenza—followed by a touch of neuritis." Soon, however, another attack, followed by an additional nervous lesion, supervenes, and with the appearance of still further attacks the diagnosis of disseminated sclerosis becomes established. The history of a series of such attacks one may almost say is diagnostic of the disease. Each attack may consist simply of a slight rise in temperature and a general feeling of malaise; others may be more severe, accompanied by headache, vomiting, and more rarely a convulsion. But whether mild or severe, each attack heralds the formation of a patch of sclerosis in the central nervous system. And the position the particular patch or patches of sclerosis occupy in the nervous system decides the character of the set of symptoms which immediately supervene. Thus a patch of sclerosis in the internal capsule will lead to a hemi- or monoplegia; in the parietal cortex to asternognosis; in the cerebellum to ataxia; in the mid-brain to oculomotor palsy and nystagmus; and, finally, in the medulla to spastic paresis of the limbs and trouble with speech.

If the early history in this disease is almost diagnostic, the same can be said with equal truth of the subsequent history. For after the immediate inflammatory reaction round each patch of sclerosis has subsided, the permanent damage remaining is frequently slight. Accordingly, steady improvement in the symptoms occurs after each pyrexial attack, so that marked remissions in the course of the disease are the rule, and must be expected. In the earliest stages of the disease the case is frequently regarded as one of hysteria—the sudden appearance of somewhat anomalous nervous symptoms, which ultimately almost clear up, being held as sufficient reason for this diagnosis. But if the possibility of disseminated sclerosis is kept in mind, this error should not be long sustained, for in spite of the apparently dramatic remissions which occur, definite chronic changes are all the time taking place in the nervous system, and these changes careful clinical examination will reveal. Once these chronic degenerative lesions are fully established, no treatment is of much avail. To produce any real result it is necessary to recognise the disease in its earliest stages and—if such a thing is possible—put an end to the series of harmful pyrexial attacks which indicate formation of new plaques of sclerosis.

Early Diagnosis.

Within the last two years ten early cases have come under my notice. In each case it had been noticed by the patient's doctor that complete recovery had not followed the so-called influenzal attacks, and the presence of certain symptoms had aroused grave suspicion. Brief notes of some of the cases are as follows:—

CASE 1.—Male, aged 32, woke up one morning with a numb feeling in the right leg; got out of bed and found putting his bare feet on the cold oilcloth produced no sensation of cold. He had been suffering from a chill for several days. There had been a similar condition in the left leg about two years previously. Walking was slightly difficult, legs tired easily, right leg dragged; cramps in the legs and frequent "tickling sensations in both feet." Some precipitancy of micturition. On examination there was clear evidence of a spastic paresis with altered reflexes on

the right side. Cranial nerves normal. Loss of sensation to hot and cold and pin prick on the right side below ninth dorsal segment. These symptoms improved in two or three weeks, at the end of which time I re-examined him. The sensory loss had disappeared almost completely—a feature in itself significant of disseminated sclerosis. Ten months later he had a sudden illness with shivering, headache, and diarrhoea—accompanied by cramp and numbness in the right leg. At this time, in addition to the right hemiparesis, there appeared slight nystagmus.

CASE 2.—Female aged 32. Two and a half years ago had a severe attack of so-called "influenza," after which she noticed the right leg became weak and she had to use a stick for getting about. Following another attack the legs became numb and there was frequency and precipitancy of micturition. On examination there was definite coarse nystagmus; slight spastic paresis of both legs also present.

CASE 3.—Female, aged 24, suddenly noticed stiffness in right arm and a numb feeling in hand. Four months previously she had had a temporary mistiness of vision affecting both eyes. Shortly after this the right leg had become stiff and weak, but rapidly improved again. Also about this time the right eye turned inwards for a short time and caused diplopia.

I do not suggest for a moment that the diagnosis of disseminated sclerosis should ever be precipitately made. The case must be carefully watched and the diagnosis deferred until sufficient clinical evidence is forthcoming. At the same time, valuable time in which treatment should be commenced must not be lost.

At this point it would be useful to summarise the main points in the early diagnosis of the disease. I would place them as follows: (1) The occurrence of repeated pyrexial attacks followed by groups of nervous symptoms which tend to improve in a few weeks; (2) age of onset (*viz.*, the young adult); (3) certain nervous symptoms—chief amongst them being slight nystagmus, temporary diplopia, paresthesia of a fleeting character, blurred speech, evidence of spastic paralysis (*e.g.*, absent or diminished abdominal reflex on one or both sides), exaggerated deep tendon reflexes with extensor plantar reflex on one or both sides—any or all of which symptoms may be transient; (4) negative Wassermann reaction; (5) a paretic type of curve with the colloidal gold reaction—this being, in my experience, an inconstant phenomenon.

Review of Methods of Treatment.

Before turning to a short review of the methods of treatment which have been advocated, it is important for us to realise that, owing to the marked remissions which occur naturally in the disease, we must beware of the probability of such a remission of symptoms coinciding with the commencement of a particular line of treatment. One cannot help feeling that in this coincidence lies the explanation of the claimed success for numerous forms of treatment—forms which include a lengthy list of drugs, also vaccine therapy, injections of fibrolysin, &c. Of drugs, the following have been advocated and given extensive trials: Arsenic, zinc sulphate, iodides, mercury, silver nitrate, quinine, salicin, and lastly, cod-liver oil—a notley list. An interesting commentary on this list is provided by Oppenheim's statement that poisoning by lead, arsenic, and mercury may even predispose to the disease. The stalwarts of homoeopathy might well seize on this instance for their own advancement, in the article on disseminated sclerosis in Clifford Allbutt's "System of Medicine" the position is summed up in the following terse statement: "The therapeutic prospects in disseminated sclerosis are gloomy in the extreme." And, indeed, there can be little doubt that the success which has been attributed to certain remedies is mainly due (1) to the remissions which independently occur in the disease, and (2) to the dissipation of certain hysterical aggravations of the organic symptoms—as has been insisted on by Dr. A. F. Hurst. Active suggestion in such cases will produce more defined and more complete improvement than any drug.

The Infective Virus.

Let us consider for a moment what our aim is in the struggle with this disorder. It is clear that very little improvement can be hoped for once the nervous system has become riddled with small patches of sclerosis. A form of treatment is needed which will grapple with the virus and stem its advance in the early stages of the disease. From this point of view it seemed at one time that treatment with some form of vaccine would successfully curtail the disorder. Accordingly, autogenous vaccines from micro-organisms obtained from various infected sources in the body (more especially from the alimentary and genito-urinary tracts) have been used—the assumption being that the toxins of such organisms circulating in the blood lead to disseminated inflammation in the nervous system. I have a fear, however—which may not perhaps be altogether justified—that the use of vaccines in disseminated sclerosis is not altogether free from serious risk.

The fact is that we are still in the dark as to the exact nature of the virus. We know that its lesions are confined to the nervous system, wherein it differs widely from the virus of syphilis. Within the past few years a spirochaete has been isolated from the cerebro-spinal fluid of patients dying of the disease, but more recent investigation still has failed to confirm this observation. One attempt which was made last year in conjunction with the late Dr. Eastwood—the cerebro-spinal fluid taken from a patient during an acute attack—failed to produce any effect whatever when introduced into the anterior chamber of the eye of a rabbit. To all appearances the fluid was non-irritating, non-infective, and non-toxic.

Recent Experience with Arsenical Preparations.

The course and character of the disease, however, point very strongly to the presence of an infective causative agent. Clinical experience over many years pays tribute to the value of arsenic when given over a long period. After the introduction of intensive arsenical treatment for syphilis it was only natural that it should be suggested that such intensive treatment would be of use in disseminated sclerosis. During the past two years I have used this treatment in all the early cases of disseminated sclerosis which have come under my notice. They number in all ten cases. The procedure has been a course of six weekly intravenous injections of novarsenobillon (0.15, 0.3, 0.45, 0.45, 0.6, 0.6), which is repeated at the end of six months. In the interval and for a year subsequent to the second course of injections, the patient is given arsenic by the mouth in the following manner: He is told to take a mixture containing 3 minims of liq. arsenicalis three times a day during alternate fortnights. This is as recommended by Dr. Farquhar Buzzard.

It is necessary to take the usual precautions in examining the patient before the first injection of salvarsan is given. In my series of cases I have not met with any untoward effect as the result of the injections. That seems to me to be by no means a negligible point in their favour; they produce no harm similar to the provocative reaction occasionally seen in the treatment of neurosyphilis. As to the amount of good they do, my experience so far has been hopeful. There has seemed to be a definite effect produced in all cases on the number and the severity of the attacks of relapses in the disease. Only two cases have continued to progress unfavourably—in the remainder the active infective process seems to be held and no further symptoms have developed.

To draw conclusions from such a short series of cases and over such a short period would not be justifiable. But in a disease where all other forms of treatment leave us with a feeling of helplessness it has been a hopeful proceeding to meet with one form which seems to exert some action towards the definite arresting of the pathological process. This note is given in the hope that others may use similar treatment and later compare results.

HYPERTHYROIDISM AS A CAUSE OF SEVERE UTERINE HÆMORRHAGE FOLLOWING MINOR VAGINAL OPERATIONS.

By ALECK W. BOURNE, M.B., B.Ch. Camb.,
F.R.C.S. Eng..

OBSTETRIC SURGEON TO OUT-PATIENTS, ST. MARY'S HOSPITAL,
LONDON, ETC.

IN THE LANCET of March 18th, 1922 (p. 530), a paper was published by Sir John Phillips describing four cases in which severe uterine hæmorrhage followed minor vaginal operations. At the time I was engaged with Dr. C. M. Wilson in an attempt to establish hyperthyroidism as a cause of so-called "functional" menorrhagia by measurement of the basal metabolic rate. Our work, which has since been published, furnished evidence that most cases of menorrhagia in young adults without physical signs in the pelvis are associated with hyperthyroidism as measured by the basal metabolic rate. By the use of an exact method we sought to prove not only the presence but also the exact degree of hyperthyroidism.

While reading Sir John Phillips's paper, though I had no personal experience of the condition he described, I was impressed by the possibility of hyperthyroidism being the cause of these apparently unexplained hæmorrhages, not only because I was, at the time, considering uterine hæmorrhage from the thyroid point of view, but also because the first case detailed by Sir John Phillips developed Graves's disease some 15 years after the attack of hæmorrhage. My interest in the subject was reawakened recently by coming into contact with a case of severe hæmorrhage, such as Sir John Phillips describes, in which Dr. Wilson has demonstrated a pathological degree of hyperthyroidism by his measurement of the basal metabolic rate.

The details of the case are as follows:—

The patient complained of dyspareunia since marriage a year ago. On examination her pain was found to be partly due to a tight hymen, and partly to prolapsed ovaries and retroverted tender uterus. The patient was emotional, easily prone to exaltation or depression, and distressed by the possibility of childlessness. On Dec. 9th, 1922, I removed the hymen, enlarged the vaginal orifice by a short posterior incision, and suspended the uterus and ovaries by shortening their respective ligaments. The uterus was not dilated or curetted. Menstruation had finished a few days before the operation was done.

There was no trouble until the morning of the fourth day, about 10 A.M., when suddenly I was urgently sent for on account of a severe hæmorrhage escaping from the vagina. On arrival, within an hour from the onset, I found the patient pallid and anxious, with an increased pulse-rate, and a large quantity of blood-clot on the bed. There was still free bleeding and it was considered necessary to plug the uterus immediately. Under anaesthesia a speculum was passed and the small perineal wound was carefully inspected and found to be quite dry and healing satisfactorily. The vagina was full of clot, and after clearing this away blood was seen issuing from the closed os. The cervix was thereupon dilated with Hegar's dilators, and the uterine cavity tightly packed with gauze. This was followed by a hypodermic injection of "femergin" and administration of saline by rectum.

The plug was removed the next morning, but there was no further bleeding either then or at a later date during the convalescence. Suspecting a thyroid origin for this unexplained hæmorrhage, I asked Dr. Wilson to measure the basal metabolism. On Feb. 21st, 1923, he found it to be +18 per cent., and a repeated measurement on the 24th gave +18.5 per cent.

In a previous paper¹ we have shown that "functional" menorrhagia is very commonly associated with a basal metabolism reading of from +16 per cent. to +25 per cent., which we have ventured to accept as evidence of at least an association and possibly a causal relationship between hyperthyroidism and this variety of uterine hæmorrhage. In addition to the sudden bout of hæmorrhage described above, this

patient has suffered from irregular and profuse menstruation, sometimes lasting for two weeks in each month, since July, 1922. A possible explanation of the post-operative hæmorrhage is that the anticipation and dread of an operation, amounting to a state of fright, reacted on the thyroid, already in an unstable condition, stimulating it to an excessive or aberrant activity.

POST-MORTEM FINDINGS IN TWO CASES OF HYDROCYANIC ACID GAS POISONING.

By G. R. SEAGER THOMAS, M.B., B.Ch. Camb.,
HONORARY PATHOLOGIST, ROYAL SOUTH HANTS AND
SOUTHAMPTON HOSPITAL.

AFTER fumigation of a ship with hydrocyanic acid gas the hatches and ports are opened and the gas allowed to escape. When a certain period has elapsed a clearing gang goes through the ship to disconnect the gas-producing apparatus and to perform various other duties. These men are equipped with gas-masks, oxygen reservoirs, and cages of rats and mice. On the occasion of the fumigation of a large liner at Southampton on July 30th, 1922, two of the men in the clearing gang were fatally gassed. I performed post-mortem examinations upon them in the presence of other medical men on August 1st at the Royal South Hants and Southampton Hospital.

The circumstances of and facts concerning these cases are of great interest from clinical, industrial, public health, and medico-legal points of view. I understand, however, that a memorandum of the cases will be included in a paper on fumigation with HCN shortly to be published, and I therefore restrict this report to an account of the post-mortem findings, which it is desirable to place on record in view of the comparative paucity of definite information at present available on the subject in medical literature.

The reports of the autopsies are tabulated side by side to make more clear the strict parallelism of the conditions observed.

W. C., male, aged 40.

Extreme lividity over face, neck, upper half of trunk and all dependent parts of the rest of the body and limbs. Colour a vivid delphinium blue. Nails blue.

No odour of HCN perceptible before the body was opened.

Body and limbs rigid.

Pupils dilated, but not widely. Chemosis and injection of conjunctivæ, which were deep pink in colour.

Extensive separation of corium over upper half of thorax in front, and one or two blisters containing clear, very faintly pink-coloured serous fluid on trunk and scrotum. Penis and right scrotum much swollen. This swelling was due to gas in loose connective tissue of penis and scrotum, and in the right tunica vaginalis. On cutting into these structures the gas escaped, smelling strongly of HCN, and the swelling entirely subsided. No hernia or patent inguinal canal found.

Abdomen tensely distended and tympanitic. On incision into peritoneal cavity, which contained no fluid, gas escaped under considerable pressure. This gas smelt of HCN, but did not smell putrefactive.

Intestines were of a distinct pink colour, and distended with gas. When the small intestine was incised a smell of HCN was apparent. This was not perceived when the large bowel was opened.

A. C. O., male, aged 45.

Intense lividity of face and neck, the colour being the same as in the case of W. C. All dependent parts of body pink. Nails blue.

No odour of HCN perceptible before the body was opened.

Body and limbs rigid.

Pupils dilated, but not widely. There were chemosis and injection of conjunctivæ, which were pink in colour.

Subject well covered with subcutaneous fat; fat also abundant in omentum, mesentery, and perinephric regions.

Abdomen tensely distended and tympanitic. On opening the peritoneal cavity gas escaped under considerable pressure and emitted a strong odour of HCN. No free fluid in peritoneal cavity.

Intestines were pink in colour and distended with gas. No smell of HCN was observed on opening either the small or the large bowel.

¹ Wilson, C. M., and Bourne, A. W., THE LANCET, 1922, i., 1038.

W. C., male (*continued*).

Stomach pink in colour, and contained partially digested plums; no odour of HCN noticeable on opening. In region of the fundus posteriorly, a considerable extravasation of blood into tissues of stomach-wall.

Liver slightly cirrhotic, small, and of a uniform deep blue-green colour.

Kidneys were livid and engorged.

Suprarenals very soft and degenerate.

Spleen engorged with dark blood, and a small spleniculus was present.

Pancreas appeared normal. Bladder half-full of urine, which did not smell of HCN.

On opening pleural cavities, a distinct smell of HCN.

On opening pericardium, a noticeable smell of HCN.

Valves of heart normal. Right side of heart engorged; endocardium pink, myocardium flabby.

Aorta appeared healthy throughout, but showed bright pink staining.

Mucous membrane of mouth, tongue, pharynx, oesophagus, larynx, trachea and bronchi engorged and livid. Slight oedema of vocal cords. No mucus seen in trachea. Lower third of oesophagus distended with semi-digested plums.

Lungs intensely engorged with dark blood; smell of HCN on section.

Over right occipito-parietal region a contusion with slight extravasation of blood into tissues of scalp. No fracture seen.

Grey matter of brain, especially basal ganglia, stained a deep clear green (sage-green) colour. White matter had a faint bluish tinge, grey matter showing up against it in most distinct and beautiful demarcation.

On section into lateral ventricles a marked smell of HCN. A stronger smell of gas than in any other part of body; estimated as stronger than that experienced on smelling a bottle of the B.P. acid.

In both cases marked absence of putrefaction; absence of putrefactive odour of gases and organs; absence of ordinary post-mortem discolorations. Blood from lungs examined, and a spectrum corresponding to that of cyanhamatin obtained. Fluid from lateral ventricles, and scrapings from walls of lateral ventricles, portions of optic thalami, lungs, and liver examined chemically and yielded positive results to tests for cyanides.

It seems worth while to emphasise the outstanding features which are common to both cases—viz.: Absence of smell of HCN before opening the body, and absence of this smell from the urine; gaseous distension of peritoneal cavity and of intestines; smell of HCN in all serous cavities; concentration of smell of HCN in lateral ventricles; intensity and precise colour of facial lividity; blue nails; pink colour of intestines and gastric mucosa; bright pink staining of intima of the aorta; uniform blue-green colour of the liver; green colour of grey matter of the brain; colour and chemosis of the conjunctivæ; lividity and engorgement of buccal, pharyngeal, oesophageal, and respiratory mucous membranes; extravasation of blood into the tissues of the stomach-

A. C. O., male (*continued*).

Stomach almost empty; mucosa bright pink in colour. Strong odour of HCN on opening. An extensive extravasation of blood into tissues of stomach-wall in region of the fundus posteriorly.

Liver a uniform deep blue-green colour except for slight mottling with yellow over portions of surface, where there was a slight superficial hepatitis.

Kidneys injected and slightly granular.

Suprarenals appeared normal.

Spleen enlarged and engorged with dark blood, and presented one small superficial scar.

Pancreas appeared normal. Bladder about one-third full of urine, which did not smell of HCN.

On opening pleural cavities, a distinct smell of HCN. Extensive old pleural adhesions on both sides.

On opening pericardium, a noticeable smell of HCN.

Right side of heart slightly engorged, left side empty; endocardium was normal in colour; very slight sclerosis of mitral valves; myocardium flabby.

Aorta appeared healthy throughout, but was stained a very bright pink.

Mucous membrane of mouth, tongue, pharynx and oesophagus engorged and livid. Larynx, trachea, and bronchi injected; slight oedema of vocal cords. Larynx and trachea lined with frothy mucus.

Lungs engorged with dark blood, except for scattered patches of a bright pink colour, and one or two small collapsed areas. Smell of HCN on section.

Grey matter of brain was stained green, not so deeply by any means as that of W. C.; the colour in this case a light olive-green.

On section into the lateral ventricles a marked smell of HCN, even stronger than in the case of W. C.

wall posteriorly in the region of the fundus; flabbiness of the myocardium; absence of putrefactive changes, of putrefactive odour, and of the ordinary post-mortem staining; and positive chemical and spectroscopic tests.

FIBROMA OF THE OVARY,

WITH AN ACCOUNT OF A CASE.

By AMBROSE W. OWEN, M.D., B.S. LOND.,

HON. SURGEON, ABERDARE AND DISTRICT GENERAL HOSPITAL.

FIBROMATA of the ovary are comparatively rare. Maclean¹ quotes Bland-Sutton as terming them "pathological curiosities." Clark and Gabe of Indianapolis, in a recent report of a case, note that very scant reference is made to the condition in most gynaecological text-books. They produce statistics to show the rarity of the condition. Thus, Sir Spencer Wells in 1200 ovariectomies found only three cases of ovarian fibroma, Kelly in 1200 laparotomies found four, whilst Hellman reports but six cases out of a series of 4500 pathological specimens covering a period of ten years at the Frauenklinik of the Charité at Berlin. Clark and Gabe's conclusions after a very thorough review of the literature on the subject are as follows: (1) Ovarian fibromata are sufficiently rare to warrant the publication of all carefully studied cases; (2) the diagnosis is dependent solely on microscopic examination; (3) in the presence of a hard, unilateral, movable tumour with ascites, where the more common causes of ascites can be ruled out, ovarian fibroma is highly probable; (4) the treatment is operative, the prognosis good.²

Incidence and Symptoms.

Ovarian fibromata are generally said to comprise 2 per cent. of all ovarian tumours. They occur at all periods of life, but are most common in single women about the menopause.³ The youngest case I have seen mention of—a girl of 12—is referred to by Eden and Lockyer.³ McCann reported the oldest case—a woman of 73.⁴ The clinical feature of a hard, one-sided, mobile pelvic tumour with ascites is very characteristic of the condition, but the presence of ascites is, however, very inconstant. It occurred in one only of seven cases collected by Fairbairn⁵—that is, in 14 per cent.—whereas Doran⁶ met with it in 5 out of 11 cases—45 per cent. Hellman states that only 5 per cent. of the cases show ascites.³ When present it may be extreme and require repeated tapplings. It was fairly extensive in the case now reported. Many explanations—mechanical, chemical, secretory—have been offered to account for its presence, but it is an extraordinary thing that it is not seen with other benign ovarian growths or with similar fibroid growths of the uterus. Hydrothorax may occur with the ascites. Other symptoms, such as pain, vomiting, dysuria, are the result of pressure, and naturally vary with the amount of ascites and the position and size of the growth. The latter may vary from that of a hen's egg to that of a man's head, though examples weighing as much as 56 lb. have been recorded. Apparently the microscopical examination of these tumours, which is laid down by Clark and Gabe as being the sole criterion of an accurate diagnosis, is not a simple matter. Williamson,⁷ for instance, points out that the microscopical examination is not always to be relied on, and that growths which on their microscopy were thought to be innocent have turned out to be malignant. As he says, "more accurate deductions as to the innocent or malignant nature . . . may often be drawn from the gross rather than the microscopical characters."

Classification.

Following Fairbairn's pioneer work, it is customary to divide these growths into three classes: one of these, the small pedunculated fibroma, accounts for a very small proportion of all the cases. The other two classes are defined by the amount of ovary

involved in the pathological change. When no trace of normal ovary tissue can be found, the growth is called a "diffused fibroma," and the great majority are said to be of this nature. It is in this class that some assert that ascites is the rule, but as they form the majority of cases, then we would expect to find ascites present in the majority, which is apparently not the case—Hellman stating that it only occurs in 5 per cent.² This figure may be low, but Doran's and Fairbairn's are also too low if the rule is to hold good. When only a part of the ovary is involved in the "fibromatous" process it is common to find a capsule to the growth, hence the name "encapsuled fibroma" given to this third class by some. These encapsuled growths are always innocent, and according to some are "seldom or never accompanied by ascites."⁷ As will be seen later, however, my case had a well-marked capsule and a considerable amount of ascites. Clark's case had a "well-marked fibrous capsule," and some ascites, though the latter was not recognised clinically.² These growths do not separate the layers of the broad ligament; they possess a pedicle which is rather short and broad as a rule.¹ Their consistence varies from soft—when degenerated—to bone-hard. Like uterine fibroids, they are liable to degenerative changes of which the commonest are cystic (due to myxomatous softening or to hæmorrhage), calcareous, and œdematous. The pedicle may become twisted³ and, of course, the growth may obstruct labour.

An Illustrative Case.

A case I treated recently is, I think, worth recording.

A married woman, aged 52, sent for me on Jan. 5th, 1920, on account of pain and swelling in the abdomen. The duration of her trouble she put at about two years. My notes at the time read: "Menses 19-51. Never any disturbance of this function. Eight children living—two are twins—says she has had over 20, twins twice and triplets once (?)"

Condition on Examination.—Mountainous swelling of abdomen due to free fluid and hard tumour, more on left. Mobility difficult to make out—so much fluid. P.V.—Cervix high up, jammed against back of pubes. Uterus seems separate from tumour (she says latter moves from side to side). No œdema lower limbs, vulva or lower abdominal wall. No nodules anywhere. Small ventral hernia—had it for years. Anæmia and cachexia, but has suffered for a time from pain, dyspepsia, and palpitation, with consequent loss of sleep. Pulse rapid and feeble. T. normal. Urine normal (never any dysuria). Diagnosis: On account of ascites, solid tumour of the ovary probably a fibroma; on account of certain amount of cachexia present—possibly sarcoma. I advised removal of the tumour or in default, tapping of the abdomen. After some hesitation the patient consented to be tapped.

Paracentesis.—On March 1st, at the Aberdare and District General Hospital, I performed paracentesis and withdrew 7½ gallons of clear greenish fluid. The tumour could now be felt as a hard, rounded, ballotable mass filling up a considerable part of the abdomen. As a general anæsthetic was employed, the patient being very apprehensive, the separability of the tumour from the uterus was made abundantly clear. No nodules were felt anywhere. The patient felt so relieved she would not consent to a radical operation and was discharged on the 19th.

Course of Case.—I saw little of her until I was sent for again on Jan. 25th, 1921. She had been suffering for some time from pain and intractable bilious vomiting due to pressure, which had made her life miserable; she was now prepared to have anything done. She was thin and wasted, but not to the extent I should have expected after such an interval had the growth been malignant. There had been a reaccumulation of fluid, but to nothing like the quantity present before tapping. The tumour had grown considerably; I thought it roughly one and a half times as large when she was in hospital. Vomiting was extreme—cold water being rejected as soon as taken. The pulse was rapid and feeble and temp. subnormal. The maximum abdominal girth was now 55 in. The similar figure previous to tapping I lost. There were no other new physical signs.

Laparotomy.—She was admitted to the same hospital again on Feb. 9th, 1921, and on the 12th I performed laparotomy with the help of my colleagues Dr. Isaac Banks, who assisted, and Dr. J. C. Ogilvie, who gave open ether. A small nick in the peritoneum allowed 22 pints of ascitic fluid, similar to the previous discharge, to flow slowly.

The incision was then enlarged well beyond the umbilicus and the tumour seen occupying the greater part of the abdomen. It was covered with a greenish-yellow, semiglistening, smooth surface very similar in appearance to the non-sensitive side of an undeveloped photographic film. Flakes of a similar nature to the covering of the tumour were floating loose in the ascitic fluid remaining, as if they had been rubbed off by friction. There were no adhesions, and the tumour, which was found to be of the left ovary, was removed whole by ligating the very short and broad pedicle by which it was attached in chains. The uterus and right ovary, which appeared normal, were allowed to remain. No nodular or papillomatous growths were seen in the abdomen, which was closed in the usual way. When examined in the bowl which received it the tumour resembled a huge pumpkin in shape, being rounded, and flattened from top to bottom. It was much larger than a man's head. The largest circumference was 41½ in. It weighed 19½ lb., and was soft and compressible. The covering of greenish-yellow tunica albuginea or capsule, after incision, was stripped off the whole of the tumour with the greatest of ease. The collapsed shell of the tumour, after stripping, showed at one pole a knob-like projection which looked as if it might have been the remains of the ovary, but unfortunately this portion was not examined microscopically. On section the tumour was honeycombed with small (½ in. diameter) cyst-like spaces which exuded blood freely and were evidently areas of degeneration.

Pathological Report.—A portion of the tumour was sent to the Clinical Research Association, and the following report was received: "The tissue is entirely necrotic and cellular elements are made out with great difficulty. It is a fibro-myoma (? fibroma, A. W. O.) of the ovary into which hæmorrhage has taken place thus forming the cysts, and subsequently the whole tumour has undergone necrosis. There is no evidence of recent infection. There is no sign of malignancy or of innocent epithelial proliferation." The patient was discharged from hospital much improved on April 30th, 1921.

I recently examined her—on April 20th, 1923, just 26 months after removal of the tumour—and found a rosy-cheeked, smiling and very obese woman (her obesity, she stated, was marked before her illness), and any doubts I had as to the real nature of the tumour were dispelled the moment I saw her. I could find no evidence of recurrence of the tumour or the ascites. The large size of the former and the extent of the latter are of interest. I could detect no hydrothorax. Unfortunately, by a mistake the tumour was destroyed a few days after removal. It would, I think, have been a useful addition to any gynecological museum.

TWO SPORADIC CASES OF INFECTION BY B. AERTRYCKE.

BY DOUGLAS FIRTH, M.D. CAMB., F.R.C.P. LOND.
JUNIOR PHYSICIAN, KING'S COLLEGE HOSPITAL;

AND

E. FF. CREED, B.M., B.Ch., D.P.H. OXF.,
DIRECTOR OF THE PATHOLOGICAL DEPARTMENT,
KING'S COLLEGE HOSPITAL.

THE connexion between *B. aertrycke* and food poisoning is now so well established that this organism is one of the first to come under suspicion when an outbreak of food poisoning occurs, but difficulty often arises in the recognition of the sporadic case, either from anomalous symptoms, or from insufficient pathological investigation when abdominal signs are preponderant.

The first case here recorded may be taken as representing the usual type, in which sudden onset, pyrexia, diarrhoea and vomiting, general abdominal

pain, and marked tenderness on palpation over the whole abdomen are the usual features. These are, however, by no means pathognomonic, and as a rule it is only by a process of exclusion, and with the help of the pathologist, that a correct diagnosis is reached. This case was sent to hospital as an "acute abdomen" and reached the medical wards with a provisional diagnosis of atypical typhoid fever, but clinical evidence and pathological investigation soon corrected this error. In the second case, no suspicion of the causative agent was roused, although some form of poisoning was suspected, and it was only after the examination of cultures from the cadaver that *B. aertrycke* was implicated. In neither instance was any other member of the household affected, nor was the source of the infection traced.

CASE 1.—Male, aged 23, admitted to King's College Hospital on August 1st, 1922, complaining of severe abdominal pain, with vomiting and diarrhoea which had started suddenly 24 hours previously. The abdominal pain was sharp and stabbing in character, but not definitely localised. It remained a prominent feature throughout the first week. Vomiting was frequent at the onset and did not finally cease until the seventh day; diarrhoea persisted for about the same time. The tongue was dry and the dorsum furred. The abdomen was moderately distended, and there was marked general abdominal tenderness without rigidity. Headache was severe for the first few days. The temperature was 102° F. on admission and gradually fell, becoming normal on the eighth day. The pulse-rate never rose above 100 and for most of the febrile period was between 80 and 90. The atropine test was performed on the third day, and the maximum increase in pulse-rate under the influence of 1/33 gr. of atropine was 14. A blood count on the third day showed a total leucocyte count of 14,400 per c.mm., with polymorphonuclears 67.6 per cent., lymphocytes 31.2 per cent., eosinophiles 1.2 per cent. The pyrexia and symptoms all subsided by the end of the first week, and convalescence was uninterrupted.

Bacteriological Investigation.—A blood culture was taken on the day after admission, Douglas and Colebrook's tryptic-broth culture-medium being used, but the cultures remained sterile. A Widal test on the patient's serum to *B. typhosus* and *B. paratyphosus* A and B was performed with negative results. On the third day a specimen of faeces was plated out, and from this *B. aertrycke* was isolated and identified. About 50 per cent. of the colonies developing on MacConkey's medium proved to be *B. aertrycke*. The organism gave all the cultural reactions of the Salmonella group; it was not agglutinated by a *B. paratyphosus* B or a *B. gaertner* serum even at one-tenth of the full titre of the serum; but gave standard agglutination with a *B. aertrycke* serum at double the titre of the serum. These agglutination reactions remained unchanged after the organism had been grown on artificial media for four months. Attempts were made to isolate the organism from the stools during the second and third weeks of the disease both by direct plating and by brilliant-green enrichment methods, but without success. Unsuccessful efforts were also made to recover the organism from the urine.

The agglutination reactions of the patient's serum gave the following results:—

Date in 1922.	Day of disease.	Standard agglutinin units.	
		<i>B. aertrycke</i> .	<i>B. paratyphosus</i> B.
Aug. 10	11	1760	6
" 21	22	1760	19
" 29	30	880	22
Sept. 12	44	270	6
Oct. 19	81	68	4
Nov. 30	123	44	<4

There was throughout no development of agglutinins to *B. paratyphosus* A or to *B. gaertner*. All agglutination tests were performed by Dreyer's method, with standard cultures and sera issued by the Oxford University Pathology Department.

CASE 2.—Female, aged 8, admitted to hospital at 9 P.M. with the following history: The day previous to admission the child seemed quite well, but at 3 A.M. had been roused with an attack of vomiting, soon followed by diarrhoea, which became severe and was accompanied by great pain in the abdomen and back, and marked restlessness. During the afternoon the child became unconscious, in which state she was admitted to hospital. On examination, the temperature was 101° F., respirations 60, and the pulse uncountable, but no abnormal physical signs could be detected. At 10.30 P.M. there was a generalised convulsion

with twitching of the arms and legs. A second occurred at 12.40 A.M., during which head retraction was marked, the opisthotonos being so severe that the head nearly touched the heels. The pupils were widely dilated and immobile during the fit, but became normal soon after the attack had ceased. A third fit occurred at 5.30 A.M., in which the opisthotonos was again marked; the respirations then became rapid and irregular, and the child died at 5.40 A.M., some 28 hours after onset of illness. Post mortem a marked injection of the mucosa was found in the stomach and duodenum; this subsided in the jejunum, became more intense in the ileum, and reached a maximum in the lower ileum and caecum, where the appearance was hæmorrhagic. The inflammation died away in the descending colon. The spleen was large and soft, and the mesenteric glands were increased in size. Apart from some congestion of the lungs and brain, no other lesions were found. Dr. J. G. Ledingham isolated *B. aertrycke* from the spleen and intestinal contents.

We are indebted to Sir Humphry Rolleston for permission to publish the notes of the second case.

A CASE OF ENCEPHALITIS LETHARGICA

RECOGNISED BY CHANGE IN BEHAVIOUR.

By JESSIE H. GELLATLY, M.D. EDIN., D.P.H.,
ASSISTANT MEDICAL OFFICER OF HEALTH, CAMBRIDGESHIRE
COUNTY COUNCIL.

FOLLOWING the publication in THE LANCET¹ of Prof. A. J. Hall's Lumleian lectures, notes of the following case were sent to him. He was kind enough to give his opinion that it was undoubtedly an example of encephalitis lethargica, and suggested its publication as illustrating particularly the serious medico-legal aspects of these cases.

Family History and Circumstances.—The child, a girl, aged 10 years and 10 months, is illegitimate, born when the mother was 17 years old. The mother is of average intelligence for her class; no abnormalities are known in her family nor in that of the child's father. The mother has married since the birth of this child; the step-father has always rather resented the latter's presence in the home, and has never treated her kindly. The home is a very poor one in every respect.

Previous Personal History.—Until early in 1920 the child, although described afterwards by her teacher as rather nervous and excitable, was never noted as in any way abnormal, and her general intelligence was certainly quite up to the average of her age and class.

Present Illness.—Early in 1920 the child was suddenly seized with what was then diagnosed as a violent attack of chorea. I did not see her until some months afterwards, when an accurate history was a little difficult to get from the relatives, but one fact had struck them very much, and can be relied upon—namely, that for the first 24 hours the child saw everything double. The illness was said to have come on through a fright—seeing a favourite uncle fall off a horse. The night after this fright she was very excited and hardly slept at all; the choreiform movements developed next day, and on (I think) the following day a doctor was called in who sent her to Addenbrooke's Hospital, Cambridge. She remained there, under treatment for chorea for about a week, but was discharged at the end of that time as "nobody could get any sleep in the ward, she made so much noise all night." She was treated as an out-patient for some months; the choreiform movements gradually subsided, but the child has remained in a very markedly abnormal mental state ever since.

Condition on Examination.—I saw her first in February, 1921, when she had returned to school. The parents had had no medical advice for some months. The child was then nearly nine years old; her general intelligence was good, and her school work nearly equal to the average for her age in spite of her long absence. She was, however, very restless, talkative, excitable, and emotional, the teacher said, "quite different from what she used to be." The parents complained that she gave them no rest at night, and that she was very spiteful towards the other children. Definite statements were made that as bedtime approached she became very excited, and although sent to bed sat up shouting and singing most of the night. She would fall asleep about breakfast-time, and often sleep until midday. The parents were utterly out of patience with the child, and had treated her with considerable severity on account of

¹ THE LANCET, April 14th, 1923, p. 731.

the way she behaved at night, but without any effect. About this time she was seen by the local doctor, who obtained the opinion of the superintendent of the local asylum; no definite diagnosis was arrived at, but removal from home was advised. The Education Committee arranged for her to be sent to the Lady Chichester Hospital at Hove, where she remained six months, and improved considerably, being apparently almost normal on her discharge in October, 1921.

Course of Case.—In February, 1922, the parents asked that I should see her again, as they "could do with her no longer." The nocturnal restlessness was again marked, although not so bad as before, and the child was described as quite unmanageable. The headmistress said she was exceedingly troublesome in school, and wished her to be excluded. She wept on the slightest provocation, was quite unable to concentrate on the simplest work, and was constantly drawing attention to herself by loud talk, laughing, singing, &c.

The nocturnal restlessness has gradually passed off, but the child remains most unstable and unmanageable. She

was placed for a time through the efforts of the local Voluntary Association for Mental Welfare under the care of a retired trained nurse, who had to send her home after a few weeks as the neighbours complained of her violent screaming attacks.

The child began to menstruate at the age of 10 years and 1 month, and has recently shown some tendency to exhibitionism; the mother is quite unable to cope with her, and unwilling to attempt it again. The child is now in the local workhouse infirmary, but the authorities are unwilling to keep her there as, although she is distinctly quieter, she is still a great source of disturbance and very quarrelsome. The possibility of certification under the Mental Deficiency Act has been considered, but very few institutions would consider the admission of a child who would be such a source of disturbance, and therefore so inimical to the progress of other children.

I am indebted to Dr. F. Robinson, county medical officer of health, for permission to publish these notes.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

A MEETING of this section was held on June 7th, Dr. T. W. EDEN, the President, being in the chair.

Dr. HERBERT SPENCER exhibited a specimen described as a sarcomatous ovarian dermoid, which consisted of a thin-walled cyst enclosing a few scanty hairs, and containing at its periphery a smaller cyst and a small mass of tissue which was found microscopically to be a round-celled sarcoma. The cyst was removed entire without difficulty from a woman of 41. The patient died 11 months later of widespread secondary growths throughout the abdomen. Sarcoma occurring in ovarian dermoids was rare. The first published case was that of Thornton in 1876; this case was interesting, as Thornton had used for the first time the "Listerian method" of operating.

Dr. Spencer also showed a specimen of a ruptured carcinoma of the ovary, a soft, solid tumour removed by unilateral ovariectomy. This patient was well, and showed no sign of recurrence six years later.

A third specimen shown by Dr. Spencer was a microscopic preparation exhibiting the effect on the Fallopian tube of torsion of an ovarian tumour. The tube from which the preparation was made was removed together with the ovary for recurrent attacks of torsion of an ovarian tumour. The epithelium of the tube, which normally was of the tall columnar variety, was in this preparation so flattened as to resemble endothelium, an effect ascribed by Dr. Spencer to the repeated attacks of torsion with resulting subepithelial hæmorrhage. This was an unusual effect which he had not observed in any other case.—Mr. L. PHILLIPS called attention to the fact that the sarcomatous process was not directly connected with the dermoid, and Dr. CUTHBERT LOCKYER suggested that the growth was a lymphosarcoma secondarily implanted on the ovary. This would account for the early appearance of generalised abdominal metastasis as well as the superficial position of the growth.—The PRESIDENT recalled that Dr. Spencer had published a case of successful amputation of the cervix for carcinoma as well as the present case of simple ovariectomy for a cancerous ovary. He felt that in spite of these successes more radical measures were indicated for malignant disease. As regards the epithelium in the third case, he pointed out that the flattening was not confined to regions in which the epithelium was stripped up by hæmorrhage, but occurred in places where it was normally attached; he therefore was inclined to regard it as an abnormality rather than

an effect of torsion.—Dr. SPENCER agreed that the sarcoma was not one originating in the teratomatous tissue of the dermoid, but considered it to be a primary large round-celled and not a secondary lymphosarcoma. The flattening of the epithelium in the third specimen he still considered as an effect of repeated torsion.

Dr. RUSSELL ANDREWS described a case of carcinoma of the cervix in a woman of 77 associated with prolapse of the uterus. The patient had for ten years worn a tight napkin to prevent prolapse of the cervix beyond the vulva. There had been bleeding for 12 months and the appearance of the prolapsed cervix was typical of carcinoma, but on account of the extreme rarity of carcinoma of the prolapsed cervix he had removed a portion for microscopic examination (which confirmed the diagnosis of carcinoma) before proceeding to perform vaginal hysterectomy. He thought it probable that the cancer resulted from chronic irritation of the cervix by the napkin.—Dr. LOCKYER could not understand why carcinoma should be as rare as it was, since it would be reasonable to expect that chronic irritation of the prolapsed cervix would lead to cancer. Only one case of the kind had occurred in his practice.—Dr. SPENCER had seen two cases of the kind, in one of which the growth was as large as a cocoanut.—The PRESIDENT was not satisfied that irritation by friction alone was a predisposing cause of cancer, and he suggested that possibly the supposed immunity of the prolapsed cervix from cancer might be merely a matter of inadequate or inaccurate statistics.

Mr. VICTOR BONNEY read a paper on

DIURNAL INCONTINENCE OF URINE IN WOMEN.

In its early stages this form of incontinence only occurred when women made some effort producing sudden violent abdominal strain, such as coughing or sneezing, but as it grew worse it was provoked by any movement which involved a sudden jerk, such as walking downstairs, running, jumping, or laughing, whilst in very bad cases the patient could scarcely make a movement of any sort in the standing position without wetting herself. Clinical examination showed that the escape of urine was associated with an abnormal descent of the bladder and urethra immediately behind the symphysis pubis. The speaker then proceeded to discuss the supporting mechanism of the female bladder and urethra, illustrating his remarks by a diagram, model, and slides. The base of the bladder rested on a layer of unstriated muscle fibres, the "pubo-cervical muscle sheet," which was attached in front to the pubic bone and behind to the cervix. This muscle sheet blended with the "peri-urethral wedge," a block of fibro-muscular tissue which surrounded the urethra. Diurnal incontinence was due to giving way of the pubo-cervical muscle sheet at its anterior end in contrast to cystocele, which was due to yielding of the middle segment of the muscle-sheet, and which did not produce diurnal incontinence, though it was popularly supposed to. In the sphincteric mechanism the sphincter vesicæ was probably

only one factor, and experiments which he had carried out seemed to show that the resisting power of the sphincter muscle varied immensely in different women. Mr. Bonney said that there still seemed to be a good deal of ignorance on the subject of diurnal incontinence, most medical men not being aware that it could be cured by operation. The common treatment was to insert a pessary, a perfectly useless proceeding, for no instrument could relieve the deformity which was the cause of the incontinence. A very large proportion of the sufferers could be cured by the operation which was called "tautening the vesical sphincter," though it really tautened the sphincteric mechanism rather than the sphincter. In a few cases where this operation had been insufficient he had attained success by ventro-fixing the bladder.

Mr. PHILLIPS inquired whether the pubo-cervical muscle sheet was not another name for the anterior fibres of the levator ani. He had performed the ordinary anterior colporrhaphy for diurnal incontinence with results which were generally very satisfactory.—Dr. SPENCER expressed surprise that Mr. Bonney had not referred to Kelly's operation, which he had often performed. After a failure with Kelly's operation he had performed the operation of twisting the urethra with success. He found it difficult to understand how the folding by transverse suturing of the pubo-cervical fascia described by Mr. Bonney could affect a muscle running antero-posteriorly.—The PRESIDENT described the operation performed by Watson of Edinburgh, which he thought resembled Mr. Bonney's, as following the lines of that described by Dr. Lockyer and himself, except that the dissection was carried further out on both sides. He failed to see how this could shorten or strengthen the pubo-cervical band. However, the section was indebted to Mr. Bonney for giving them a reasonable explanation of a very common and distressing complaint.

Mr. PHILLIPS read a paper on the

TREATMENT OF DYSMENORRHOEA.

with analysis of 100 cases. The cases, all of which were treated medically in the first instance, were divided as far as possible into clinical types. An analysis of the case papers brought out the following salient features; almost all the patients pursued a sedentary occupation, all were either single or sterile if married, and the majority had some menstrual irregularity, generally of the nature of excessive loss. Menorrhagia was usually associated with some degree of arrested development of the genital organs. No case had any organic disease. The type and position of the pain were most variable; it might be iliac, or hypogastric, or sacral; it might occur before, during, or after the flow, and sometimes during all three, when it was commonly associated with the passage of clots. Constipation was severe in half the cases. The majority of the patients were poorly developed, with weak abdominal muscles, faulty posture and breathing, and anaemia or visceroptosis, and many had other complaints such as headache, vomiting, frequency of micturition, and diarrhoea.

Pelvic examination was conducted by the rectum in the unmarried, and by the vagina in married women. The arrested development of the pelvic organs which occurred in half of the cases was one of three types: (i.) A small acutely anteverted uterus; (ii.) a small retroverted uterus, with a short anterior lip to the vaginal cervix; (iii.) a small retroverted uterus with a short anterior lip to the cervix. These were associated with poorly developed breasts and a male type of pelvis, and with menorrhagia or fortnightly losses much more frequently than with scanty menstruation.

Treatment.—(a) Fifty cases were treated with extracts of ductless glands, either alone or in combination with antispasmodics. The best results were obtained by the following combination: Mist. casc. co. daily, hormotone, 1 tablet t.d.s. for seven days before and during the period, and (if still unrelieved) phenazone, gr. v.; ext. caulophylli liq., ℥ xv.; caffeine, gr. v.; iq. chlorof. ad 5ss. every three hours, until relief was obtained (up to four days). Sometimes

tincture of belladonna or other antispasmodic was added to the mixture. Only four cases of this group, which failed to be relieved sufficiently to be able to carry on their work in comparative comfort, came eventually to operation. When the hormotone (or other ductless gland) tablets were omitted the painful periods often returned. (b) Forty cases were treated by antispasmodics alone; 34 were benefited, and the remaining six came to operation. (c) Ten cases were treated between the periods with bromides and salicylates, combined with laxatives and small nightly doses of luminal during the periods. All were relieved.

Clinical Types.

In treating these cases an attempt was made to interpret all the available information and evolve a plan of treatment based on the recognition of the following clinical types.

In Type 1 dysmenorrhœa was a disease of faulty hygiene, upbringing, and surroundings. This type was thin, anæmic, constipated, and poorly developed with visceroptosis and faulty posture and breathing. They followed sedentary lives with little exercise and fresh air. The feeble musculature of the uterus was easily exhausted and gave rise to cramp and pain when called upon to make expulsive efforts in the exhausted state. The treatment was directed to the correction of these faults. The correct mental attitude was cultivated by teaching the patient that menstruation was natural and that she must continue to bathe and take exercise as usual. No constricting clothing should be worn and stays must not be permitted to do the work of the abdominal muscles. Constipation was to be corrected by drinking plenty of water and eating fruit, combined with abdominal kneading night and morning. Purgatives should only be a temporary expedient. Exercise such as walking or tennis, and special exercises designed to strengthen the abdominal wall formed an important part of the treatment. Finally the importance of faulty upbringing and surroundings as a factor in the production of dysmenorrhœa and the need of improving these was emphasised. It was not so common to find a robust girl suffering from dysmenorrhœa.

In Type 2 the dysmenorrhœa was functional. These women complained not only of menstrual pain, but generally of headache, nausea, constipation as well. They were usually nervous and worried. Ten such cases were treated successfully by sedatives: (a) Bromides and salicylates between the periods; (b) luminal gr. i. gr. iss. nightly during and just before the period; and (c) general hygienic measures as already outlined, with attention to bowels and eyes.

In Type 3 the symptoms suggested some form of obstruction as the causal factor. This theory had been abandoned by many as it was considered that flexions and narrow os could not obstruct the flow of one-third of a drop of blood per minute, the rate of flow if 4 oz. of blood was lost in four days. However, the blood might be clotted, when obstruction would be possible in a normal internal os and cervical canal. Thin flat casts could be passed without pain, whereas solid rolled-up ones caused considerable pain. Also in some cases of dysmenorrhœa the pain was less or ceased when clots were passed. The pain resembled ureteral and biliary colic in its intensity and sudden onset, and subsided rapidly when the clot was passed, just as in biliary and ureteral colic the pain ceased when the stone was passed. Gynæcologists still continued to employ cervical splitting operations, such as anterior hysterotomy for the relief of pain. Finally, in three cases of hysterectomy for dysmenorrhœa performed during the period, the uterus was found to contain clots. Whether the intra-uterine clot was normal and was not dissolved because of endometrial defect, or whether clotting in utero was pathological, must be decided before the pain could be treated rationally. It was reasonable to suppose that a uterus with a poorly developed musculature might be unable to expel casts or clots even through a normal os.

Type 4. There was a type of patient in whom there existed "signs of arrested development of the genital organs." They complained of pain in one or other iliac region alone, or before the central pain. Menorrhagia was as common as scanty flow, because an undeveloped endometrium and musculature were linked up with a normal ovarian stimulus. The obvious treatment was to stimulate development of the uterus, and this was often successful. In addition to the general hygienic treatment organotherapy and electrical treatment were useful.

Organotherapy.—Ovarian extract, corpus luteum, thyroid, anterior lobe of pituitary, mixed gland, and hormotone (extracts of ovary, thyroid, pituitary, and testes) had been used. We know that hypothyroidism, hypo-pituitarism, and hypo-oöphorism may all be associated with pelvic hypoplasia—a condition observed in one-half of the cases in this series. Perhaps the "gatling gun" prescription like hormotone might hit the mark where the others failed. The possible part played by extract of testis was interesting. This extract alone, or combined with extract of prostate, was sometimes successful in dysmenorrhœa. In 1871 Bland-Sutton had pointed out a histological resemblance between the lining cells of the uterus and those of the large intestine, one of whose functions is chief absorption. Arthur Thomson had marshalled a formidable array of arguments to support the view¹ that the endometrium may be mainly absorptive in function.

Electricity in Dysmenorrhœa.—A few of the cases in this series were benefited by electrical treatment, but the treatment was personally administered. High-frequency currents heated up the deeply seated organs so that there resulted: (1) Dilatation of the vessels; (2) relaxation of spasm and inhibition of tone; (3) improvement in blood-supply and consequent improvement in nutrition and growth.

Results.

In ten cases where medical treatment had failed, two were cured by curettage and one by anterior hysterotomy. Hysterectomy was performed in two cases where the uterus contained clots and showed marked arterio-sclerosis, and the remainder (very severe cases) were sterilised by radium. One hundred cases treated surgically were followed up and compared with 100 cases treated medically. It was found that 25 per cent. were cured, 25 per cent. were relieved, and 50 per cent. were unaffected, while the best results were in cases treated by curettage. These results were inferior to those obtained in the series of 100 cases treated medically. The speaker believed that most gynaecologists felt that the surgical treatment of dysmenorrhœa without physical signs was on the whole disappointing.

Discussion.

The PRESIDENT congratulated Mr. Phillips upon the patient and successful work in the out-patient department upon which the paper was founded, as well as the skill with which the difficulties of nomenclature were overcome by the classification of patients by clinical types. He was particularly impressed by the small number of patients who came to operation (which in his experience cured 50 per cent., relieved 25 per cent. to some degree, and left the other 25 per cent. in no way improved) and by the greater success of medical treatment.

Mr. BONNEY pointed out that the figures of results of treatment of dysmenorrhœa were confused by the variety of causes. If dilatation was limited to cases of the "virginal type" of dysmenorrhœa described by Dr. Berkeley and himself the operative results would be much better. It was remarkable that very small uteri were so often associated with extreme hæmorrhage for which hysterectomy was required. Retroversion was often a cause of dysmenorrhœa in a virgin, and could be cured by reposition of the uterus. He intended to give hormotone a trial.

¹ Arthur Thomson: Problems Involved in the Congress of the Sexes, Brit. Med. Jour., 1922, i., 5.

Dr. ANDREWS inquired the age of the patients who were treated with radium, and the results of this form of treatment.

Dr. J. M. BRYDONE said that as a general practitioner he had been called upon to treat many cases of dysmenorrhœa, and found that while patients of 24 years or less could generally be cured, those over that age generally failed to respond to medical measures. There was a large element of suggestion about the treatment, and success was likely to follow care and perseverance. Many of the "masculine type" of women who suffered from dysmenorrhœa played too many games, and got better with rest. He described glandular treatment as achieving permanent palliation rather than cure, since relapse followed when it was discontinued.

Reply.

Mr. PHILLIPS said that the cases treated by radium were all over 35 years old, and there had been no period, and consequently no pain, in any since the treatment. It was important to keep on perseveringly with medical treatment until the right remedy was found.

YORKSHIRE TUBERCULOSIS SOCIETY.

At a meeting of this Society, held at Middleton Sanatorium, near Ilkley, on May 26th, Dr. J. RENNIE, the President, in the chair, Dr. THOMPSON CAMPBELL first demonstrated thoracoscopy on a patient having a long sinus left from tuberculous empyema, and then gave an address on cases of well-marked

Non-tuberculous Thoracic Disease Simulating Pulmonary Tubercle,

but all of which, to X ray examination, yielded findings negative of tuberculosis. There were two each of chronic bronchitis, of bronchiectasis, of pulmonary bullet wound, of pulmonary congestion plus mitral stenosis, of the sequelæ of "gassing"; and one each of silicosis, aortic aneurysm, and malignant disease. Showing in each instance a large scale schema of the physical signs, Dr. Campbell dwelt on the diagnostic points. The cases of bronchitis had a long history, ten years and four years respectively, with little constitutional impairment. The lecturer gave a reasoned attribution of the physical signs to thickened bronchioles and to alveolar catarrh. In bronchiectasis, which likewise yielded apical signs, the râles had a coarse bubbling rhonchial quality and the spit was copious and offensive; this rhonchial quality is to be contrasted with the more clicking sound common in tubercle. In cases of gassing, in the light of extended observation, diminished respiratory murmur, prolonged expiration, harsh inspiration, and muco-crepitations could very plausibly be considered as the results of simple catarrh and fibrosis. One of the heart cases showed signs in the left lung only. In silicosis the dyspnoea, anæmia, and diminished expansion, coexisting with few physical signs, helped to a correct diagnosis. In a patient with malignant disease the left upper lobe was dull, and blood-stained expectoration persisted in a way quite uncharacteristic of the hæmoptysis of phthisis. Death was due to metastatic deposits. The demonstration concluded with a display of skiagrams, including several of artificial pneumothorax cases, showing complete or incomplete collapse, in the latter case with a good view of the limiting adhesions. One skiagram of left-sided fibroid phthisis showed cardiac dislocation so marked that the intervertebral discs normally covered by the cardia were exposed and appeared in the skiagram. Time precluded more than a brief informal discussion, but the general conclusion emerged that with fuller opportunity of X ray examination of dispensary patients, such as is now available in Leeds, Sheffield, Lancashire county, and other places, these errors in diagnosis would lessen, and sanatorium beds be kept freer of non-tuberculous patients.

Reviews and Notices of Books.

THE MEDICAL ANNUAL.

A Year-Book of Treatment and Practitioner's Index. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. 1923. Pp. 600. 20s.

AN adequate review of the Medical Annual becomes more and more difficult to make, for every year—and this is the forty-first—the subjects dealt with in the Dictionary of Practical Medicine, which forms the greater part of the volume, extend over an increasing range of medical knowledge. Below will be found the names of the contributors and the main headings of the subjects dealt with by each.

Prof. E. Wyllys Andrews, Abdominal Surgery; Dr. R. Barriau, Diseases of the Heart and Blood-vessels; Dr. J. Blomfield, Anæsthesia; Dr. J. D. Comrie, Renal and Urinary Diseases; Dr. C. F. Coombs, Diseases of the Heart and Blood-vessels; Prof. W. E. Fothergill, Gynæcology and Obstetrics; Dr. Herbert French, General Medicine; Prof. E. W. Hey Groves, Orthopædic Surgery; Dr. O. C. Gruner, Basal Metabolism; Dr. J. A. Hadfield, Psychological Medicine; Colonel L. W. Harrison, Venereal Diseases; Dr. C. T. Holland, Radio-Activity and Electro-therapeutics; Dr. J. Ramsay Hunt, Diseases of the Nervous System; Dr. Robert Hutchison, Gastro-intestinal Disorders; Prof. F. S. Langmead, Gastro-intestinal Disorders; the late Dr. Arthur Latham, Pulmonary Diseases; Dr. Camille Lian, Diseases of the Heart and Blood-vessels; Lieut.-Colonel A. E. J. Lister, Eye Diseases; Dr. E. G. Graham Little, Skin Diseases; Mr. J. P. Lockhart-Mummery, Rectal Surgery; Dr. Perisson and Dr. L. Pollet, Diseases of the Heart and Blood-vessels; Dr. J. Priestley, Public Health; Dr. C. S. Read, Mental Diseases; Sir Leonard Rogers, Tropical Diseases; Dr. J. D. Rolleston, Acute Infectious Diseases; Dr. C. E. Sundell, Rheumatism and Gout; Dr. L. T. Swain, Posture Treatment; Sir John Thomson-Walker, Genito-urinary Surgery; Dr. J. A. Torrens, Asthma, Hay Fever, Tuberculosis; Sir W. de Courcy Wheeler, General Surgery; Mr. A. J. M. Wright, Ear, Nose, and Throat Diseases.

The list is an imposing one. The number of distinguished names, however, must not be taken as a sign of "highbrow" therapeutics, suitable only for well-equipped institutions. The Editor of the Annual claims, with justice, that the contributors have supplied practical and suggestive articles, and in many cases they have imparted withal a personal and critical note to help the reader in his estimate of the value of the new views presented.

There are few medical men established in practice to whom the "Medical Annual" needs an introduction. The newly qualified, while wisely clinging to their old text-books, should realise that here is a means, if they have the will, to supplement these and to keep abreast of any technical alterations or new methods as they are introduced, accepted, and come into general use. The complaint is often made, especially by country practitioners, that they get out of touch with current teaching and need periods of study-leave which they are economically unable to make. In this volume they will find the next best thing.

PRACTICAL HYGIENE OF NATIVE COMPOUNDS IN TROPICAL AFRICA.

By A. PEARSON, M.B., late Chief Medical Officer of the Tanganyika Concessions and Union Minière du Haut-Katanga; and R. MOUCHET, M.D., Chief Medical Officer of the Union Minière du Haut-Katanga. London: Baillière, Tindall and Cox. 1923. Pp. 188. 22s. 6d.

THERE are few books on hygiene, more especially hygiene in the tropics, which can be described as easy or fascinating to read; it is noteworthy, therefore, that the reader of this volume soon becomes absorbed in the essentially wise and practical outlook that is maintained throughout its pages. The book is written mainly as a guide for the medical officer, who, at newly arrived in Central Africa, finds himself confronted with multifarious and complex problems

for which his previous training has provided no solution. To the technical aspect of their subject the authors have succeeded in imparting a human touch, for a study of these pages will assist the reader to grasp the attitude of the untutored negro to European-made sanitary laws. When this point of view is thoroughly appreciated the sanitarian will find himself in a much better position to deal tactfully with situations which would otherwise be quite unintelligible.

The management of compounds where native labour is employed, implying their protection from epidemic disease to which the native workers are so prone, is becoming year by year of great economic importance. On the proper handling of the subject in the wise manner outlined in these pages the commercial future of Central Africa hangs, and no one can doubt of the enormous potentialities of the vast Dark Continent or the responsibility of British enterprise in this direction. The subject-matter dealt with is extensive. The most important sections include general considerations relating to native life; here it is explained why the "married" African fares so much better and remains healthier than his unmarried brother, how the unmarried men tend to crowd together and thereby encourage the spread of zymotic disease. The general construction of compounds receives the serious consideration it deserves, and the information given will be found full and of first-class economic importance. The situation and arrangement of kitchens, the type of hut most suitable for different conditions, the very necessary latrine arrangements, water-supplies, diet and feeding, the maintenance of cleanliness, personal and general, are all discussed in detail. There is also a section dealing with the arrangement and conduct of native hospitals. Some new and interesting information also is contained in a brief section dealing with epidemic disease and pathology.

This book should be in the hands of every medical officer in Africa who has to deal with native labour, but its lessons are pertinent outside that continent; there is much in it which applies to native labour throughout the world.

ENCYCLOPEDIA OF VETERINARY MEDICINE, SURGERY, AND OBSTETRICS.

Edited by GEORGE H. WOOLDRIDGE, F.R.C.V.S., M.R.I.A., F.Z.S. In two volumes, with 506 illustrations. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 1654. £6 6s.

Prof. Wooldridge has presented to all who are interested a detailed summary of veterinary medical and surgical diseases and their up-to-date treatments. In conjunction with a number of collaborators he has covered much ground and a large amount of information of great value is collected within the covers of these two volumes. For the graduate in human medicine, especially if engaged in public health work, the Encyclopædia of Veterinary Medicine has many points of interest. The problems of disease, such as anthrax, tuberculosis, glanders, and rabies, offer many problems for joint solution by members of the two branches (human and veterinary) of medicine.

It is helpful to the human pathologist to have some knowledge of what his colleague in veterinary pathology is doing, and the Encyclopædia might also with advantage be studied by clinicians, for many of the accepted forms of treatment in human medicine are based on observations made originally upon animal patients. Although there may be idiosyncrasies to be considered in various species of the animal kingdom, there are also many analogies, and it is upon these that true comparative pathology has its foundation.

It is by reading books such as this that the student comes to realise how much remains to be done in the vast field of animal research. The editor and his colleagues have certainly done much to assist in its advance, and credit is due to the publishers for the general appearance of the book.

THE HISTORY OF MEDICINE.

The Life and Times of Ambroise Paré. With a New Translation of his Apology and an Account of his Journeys in Divers Places. By FRANCIS R. PACKARD, M.D. London: Humphrey Milford, Oxford University Press. 1922. Pp. 297. 28s.

The School of Salernum. The English version by Sir JOHN HARRINGTON. With a History of the School of Salernum, by FRANCIS R. PACKARD, M.D., and a note on the Pre-history of the Regimen Sanitatis, by FIELDING H. GARRISON, M.D. London: Humphrey Milford. 1922. Pp. 216. 14s.

THESE two volumes are issued by Mr. Milford, who publishes in this country the books issued by the American University Presses. They are printed in the United States and we reviewed the American editions of both on their appearance in 1921.¹ The two volumes now before us being in no way different from those originally issued in America, except, if we recollect aright, that there are one or two extra illustrations to the School of Salerno as issued by Mr. Milford, we need not say anything more about their contents other than to advise strongly those who care for the history of medicine to read them.

THE CHEMISTRY OF TUBERCULOSIS.

By H. GIDEON WELLS, M.D., Ph.D., LYDIA M. DE WITT, M.D., A.M., and ESMOND R. LONG, Ph.D. Baltimore, U.S.A.: Williams and Wilkins Company. 1923. Pp. 447. \$5.50.

IN the introduction, the authors point out that in their work at the Otto S.A. Sprague Memorial Institute on the chemo-therapy of tuberculosis, they have had to accumulate and critically review preceding and contemporaneous work on the chemical aspects of tuberculosis and related problems. The last compendious work of this kind to be issued was Ott's "Die Chemische Pathologie der Tuberkulose," published in 1903. Since then a vast amount of research has been published in journals all over the world. The present volume includes a summary of Ott's work, and as complete an account as possible of the work published since then. An immense amount of time and trouble must have been taken in its preparation; the references are admirably complete and the volume is bound to form an invaluable addition to any pathological library. Moreover, a complete account of the research work carried on in the Sprague Institute is appended. The value of these researches has long been recognised, and it is convenient to have them in one compact volume.

This book will be greatly appreciated by investigators and physicians interested in tuberculosis, and Prof. Wells and his colleagues are to be congratulated on the benefit they have conferred on workers in this branch of medicine.

PRACTICAL PHYSIOLOGICAL CHEMISTRY.

Eighth edition, revised by PHILIP B. HAWK, M.S., Ph.D., Professor of Physiological Chemistry and Toxicology in the Jefferson Medical College of Philadelphia. London: J. and A. Churchill. 1923. Pp. 693. 24s.

HERE is a standard text-book containing all the chemical knowledge needed by a student of medicine. On reading the volume one is struck with the broad principles and scope of the work—a quality lacking in most books on the subject, of which, during the past few years, there have appeared a large number. There are some dozens of volumes at present on the market, all containing the particular views and even foibles of particular teachers. The familiar tests on potatoes and bread are too often copied from volume to volume with dismal uniformity, with the result that the student is tired of the subject. His interest cannot be raised on "egg-white" and

"unknowns"; he asks his teacher what bearing these experiments have on his subsequent clinical work. Anyone who has taken classes in physiological chemistry knows how difficult it is to answer these questions, and the average text-book can be sought from cover to cover without finding any reference to those chemical tests—for example systematic blood analysis, urinary diastase, and gastric analyses—in which the clinician puts his faith.

In this book every branch of chemical physiology is adequately described. One of the few criticisms to be offered is that perhaps too many methods are set out for any one determination, and no indication is given as to the one to be preferred. A full and workable account of Folin's methods of blood analysis is given and this description should go a long way towards popularising this time-saving system. The section on respiration is disappointing; a student could hardly follow the complexities of this important system from the description given. The illustrations are numerous and good.

The book should be found in every laboratory of physiological and pathological chemistry, and students will continue to appreciate it as a sound work of reference.

THE OUTLINE OF LITERATURE AND ART.

Edited by JOHN DRINKWATER and Sir WILLIAM ORPEN. London: George Newnes, Ltd. In 24 fortnightly parts. 1s. 2d. each.

PART 10 of the "Outline of Literature and Art" takes us from Shakespeare to Milton in literature, the review being practically confined to native talent, and in art deals with the Dutch paintings of the seventeenth century. These are two tremendous sections of literary and artistic activity for consideration in a very limited space, but the brief summaries seem to us to have been made with a due respect for proportion. The great medical author, Sir Thomas Browne, is treated, as he should be, more as an elaborate literary artist than as a scientist. None the less, Browne's philosophy owed as much to his continental studies of medicine and to his practical experiences at Norwich as to his classical training at Winchester and Oxford. The note on Robert Burton, whose classic, by reason of its title, so often finds its way into medical indices, shows how much proverbial humour and wisdom came from the pen of Lamb's "Fantastic Great Old Man." The note attributes to Robert Burton, among over a dozen such phrases, the following: "Rob Peter and pay Paul"; "Penny wise, pound foolish"; "All our geese are swans"; "Birds of a feather will gather together"; "Matches are made in Heaven"; and "To make necessity a virtue." Some of these brevities in wit probably had a previous origin though not perhaps in English.

It will be an excellent education for those who neither look closely at pictures nor read artistic criticism, to take the essay on Dutch painting in the seventeenth century into the National Gallery. For various reasons, despite the huge prices at sales, the paintings of these great Dutchmen are not receiving the enthusiastic attention which is their due, and which is being rendered to what are held to be more poetical or more beautiful canvasses. It will not be difficult to see both the poetry and the beauty in the national specimens, and a thing does not lose in merit because its merit is easy to detect.

AIDS TO OPHTHALMOLOGY.—A Polish translation of Mr. Bishop Harman's "Aids to Ophthalmology" has appeared. It is a translation of the sixth edition (London Baillière, Tindall and Cox., 1921) and is quite an attractive piece of book production. The illustrations and diagrams come out well and the shape of the small volume is handy. The translation has been made by Dr. W. H. Melanowski who acknowledges in the preface his gratification at being able to present to the Polish students this excellent specimen of the "Students' Aid Series."

THE LANCET.

LONDON: SATURDAY, JUNE 16, 1923.

THE COMING PANEL SETTLEMENT.

THE Panel Conference held last week at Westminster was momentous in its deliberations and in their probable outcome. The situation to-day in regard to medical practice under the Insurance Acts bears a superficial resemblance to that of 1911, for not only has the conduct of medical benefit been freely discussed, but wild and irresponsible suggestions have given rise to the idea that the whole of the panel system is again in the melting-pot. Nothing could be further from the truth. There is a crucial difference between the situation of 1911 and that of 1923. To discuss a large general proposition with any prospect of success requires not only clear vision and good judgment, but also some intimate experience of practical working. In 1911 the proposition of an insurance medical service bore a spurious appearance of orderliness based on analogy and particularly upon foreign example, with just a fringe of disorderliness of detail. In 1923 the circumstances are themselves orderly, based as they are on a body of experience, and the apparent disorderliness is spurious, to this extent, that it is due to defaults in detail which do not vitiate soundness of principle.

Let us trace the sequence of events which has led up to the Westminster panel conference. The Consultative Council of Approved Societies, with an inside knowledge of the difficulties of administration, made representations to the Ministry of Health, which were in their turn handed on to the Insurance Acts Committee of the British Medical Association, a body which constitutes the panel executive. This executive having considered these difficulties as well as all those other difficulties, real or imagined, brought forward in the public press, and having of set purpose ignored peculiar individual opinions, sent down a document embodying its considered policy to the panel committees. These in their turn, having discussed the memorandum, empowered their representatives to pronounce upon it at the panel conference. The report of this conference is set out in detail in another page of our present issue for the careful scrutiny of the medical profession as a whole, by those who are panel practitioners and those who are not, for we may frankly state that we have never attended a conference more open to the call of the common good or better devised to meet it. It was the deliberation of a body of medical men whose pleasure is in their work, and the dubious atmosphere was absent which surrounds deliberations where the intent is to find how far such-and-such a concession must be made to public opinion. With great restraint the conference refrained from discussing the amount of the capitation fee for 1924, dealing instead with the improvements necessary to ensure a first-class service in the belief that the panel doctor would then be backed up in his demand for any capitation fee which he could justify in return for such service. The conference, however, deliberately agreed to a limitation of the panel list to 2500 for a single-handed practitioner, although it was contended with good reason that the function of a supervising authority is to see that the doctor does his work properly, not to interfere with the number of

his patients. Insurance practice is not likely to benefit by discouraging its more ardent practitioners. It is undeniable that the men with large lists are often doing the best work; recent complaints have, we understand, come rather from those with short lists.

There is the complementary danger to which we have repeatedly called attention, that if the capitation fee offered is considered inadequate small panels may be given up altogether, the practitioners preferring or, indeed, being obliged to occupy their time with more remunerative work. At the present capitation rate the recompense to the rural doctor for his panel work actually does not give him a living wage, and this is a point on which more will be heard. But it is quite certain in any case that it is not by external pressure that the standard of panel work will be kept up. Panel committees may not yet be in a position to take the whole of their disciplinary work in hand, yet a beginning has been made, and the conference resolved that the regulations should be tightened up for the removal from the panel of any practitioner who, by consistent indifference to his duties, endangers the good name of the service. The fact that this new crime of "indifference" originates from panel practitioners themselves is a good omen for the future.

"UNWELL."

How unwell is the woman who is "unwell"? The discussions on dysmenorrhœa at the recent British Congress of Obstetrics and Gynæcology,¹ and at the Medical Officers of Schools Association,² reveal divergent views on what is supposed to be a very frequent disorder. We say "supposed" because whilst JACOBI is quoted as having found that pain was present in general in girls in 53 per cent. of cases, yet at a school and training centre Dr. SANDERSON CLOW found 70 per cent. of girls free from menstrual troubles, and this percentage was increased to 93 after a single educative talk with each girl. Some speakers, like Prof. BLAIR BELL, dwelt upon the pathological aspect of dysmenorrhœa and its surgical treatment, and others, notably Drs. T. WATTS EDEN, CHRISTOPHER MARTIN, J. S. FAIRBAIRN, and BETHEL SOLOMONS, laid stress upon the psychological aspects of the problem; but a crucial difference between modes of consideration of menstrual pain was unwittingly expressed by two speakers at the Congress, one of whom said, "Nobody expects the menstrual process to be free from pain entirely . . ." and the other, "If pain was not *expected* it frequently would not appear." This latter was the unanimous opinion of the speakers at the School Medical Officers' meeting, and they insisted upon the need for instruction in the elementary and essential truth that menstruation should be regarded as a natural and not a pathological function. According to Dr. CLOW, British text-books on obstetrics and gynæcology are largely responsible for the impression that suffering during the menstrual period is the rule. There is a common belief, too, among grown women that girls must expect to be in a state of semi-invalidism for two or three days in every month; but the girls themselves were easy to convert to what she calls the truer and saner view by which one of the greatest stumbling-blocks to women in their careers would be removed. "If the customary restraint on activity of girls during menstruation were withdrawn, one generation would see the end of most of the cases of dysmenorrhœa."

¹ THE LANCET, April 28th, p. 845.

² Ibid., June 9th, p. 1161.

This view of ætiology and treatment seems too simple to be true, but the changing opinions and practice in the ordinary treatment of the condition suggest that its varied though generally accepted pathology rests upon no sure foundation, and an instructive parallel is afforded by the growing belief that the pernicious vomiting of pregnancy depends upon mental processes. To her own generalisation Dr. CLOW makes one exception—"... severe spasmodic forms which had resisted treatment were not likely to yield to what she was now advocating, and to expect it would be absurd." Mr. LEONARD PHILLIPS, in a communication to a meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine, reported on p. 1215 of our present issue, deals with the treatment of these severe cases and chronicles a fair proportion of successes. In this connexion, however, we may well recall Dr. WATTS EDEN's statement at the Congress that "He had placed under observation various so-called cases of severe menstrual pain, and practically all were found not to exist." We might correlate this with Dr. W. H. B. STODDART's dictum, rather startling by its inclusiveness, in a recent communication to THE LANCET³ that spasmodic dysmenorrhœa is an anxiety hysteria. The theory put forward by Dr. CLOW sums up opinions that are gradually meeting with fuller approval, and is of great importance to the happiness and efficiency of women. The search for the causes which led to the beliefs and traditions she attacks would open up a vast field. It is clear in her opening paragraph that a usual element in psychoneurotic manifestations is not lacking, for she mentions that the treatment of the physiological state by rest in bed with a novel was followed by increased apparent morbidity. But the gain from illness is not sufficient to account for all the suffering and disability arising from the menstrual function, for it must be remembered that psychoneurotic suffering is often very real to the sufferer. We speak of puberty as a time of stress, but part of the stress is often not an inevitable phenomenon but the result of an attitude towards sex which invests it with mystery and shame. Here is a fertile soil for the growth of suggestive influences when menstruation, the function of which is not fully comprehended even by gynæcologists, first appears in a young girl carefully uninstructed in the commonplaces of physiology. The therapeutic talks Dr. CLOW gave her young friends surely removed, in some cases, fears and apprehensions which should never have been present, and which would have easily led to further symptoms. Modern ideas of education, as well as of the naturalness of natural functions, may be expected to diminish psychoneurotic disorders.

The beliefs of the parents, who, as Dr. CLOW says, are harder to convince than the girls, show the unquestioning acceptance which is the mark of traditional rather than rational influences. Of course, the menstruating girl must obey time-honoured restrictions, or disaster will follow; but the nature of the disaster is indeterminate. In some cases and countries, however, restrictions and disaster are well defined; the presence of a menstruating woman will sour the milk or spoil the meat, or lead to a speedier decay of cut flowers, and sometimes the disasters are so dread that restriction amounts to imprisonment. It is possible that relics of such beliefs have survived in our civilisation, and that our fear of injury to health by exercise during the menstrual period is a secondary explanation grafted on a primitive taboo.

THE OCTOCENTENARY AT ST. BARTHOLOMEW'S.

It would be a churlish and ungrateful knave who could not in the last week have found stimulation and good entertainment among the octocentenary celebrations at Bart.'s. Those to whom ritual makes appeal were impressed by the service in the priory church of St. Bartholomew-the-Great, Smithfield, preliminary to the solemnity held in the quadrangle of the hospital grounds. The artistic eye, however critical, could not but be well pleased by the grouping and colour scheme of the episodes in the historical pageant in the quadrangle and of the tableaux in the grand hall. The keenest epicure could not fail to be enthusiastic about both viands and service of the lunch at the Guildhall, and those to whom irresponsible gaiety is a rare treat could safely rejoice at the ill fate of those respectable members of society, whether medical knights or police inspectors, who were held for ransom in the stocks at Bartholomew Fair. Perhaps the only episode which failed to give universal satisfaction was the opening ceremony of the Fair, when academic dress was not worn and eminent surgeons and physicians in newly ironed silk hats gazed jealously at their women folk with the family umbrella. We can select only a few of the events for special notice. The service at St. Bartholomew-the-Great was as full of colour as was the church of bright academic robes, white and blue nurses' uniforms, and red cassocked choirboys. The lesson from Ecclesiasticus, starting "Let us now praise famous men and our fathers that begat us," spoken in any educational institution must stimulate all who were once pupils there, though it may need a Kipling to express the emotion it begets. After the service, the pageant passed through the square. Trumpets and drums announced the beginning of a procession, and then the Augustinian Canons now established in this country passed slowly by, chanting, stopped to pay their tribute to the monk Rahere, founder of the hospital, and passed on. The herald then proclaimed the opening of the celebrations, and the pageant, picturing episodes from the history of the hospital since its foundation, began. Of these not the least impressive was that reminiscent of the Great War, for in this generation at least, the soldiers' blue hospital uniform and all it stands for has more emotional force than any other period in history, however suggestive is its picture. Of the tableaux, too, the war episode stood out, though in grandeur it was surpassed by the episode of the granting of the charter to the hospital by Henry VII. and in sheer beauty by those pictures in which girl students from the Royal Academy of Music, dressed as mediæval ladies, lent grace and colour to the group. At the various booths of the Fair money was freely spent, with little concern for value rendered. Indeed, the cheerful spirit manifest here as elsewhere throughout the week's celebrations could be taken as a sign of the confidence that, though weather and times might be bad, Bart.'s and Bart.'s men would continue to flourish now and 800 years hence. We think it probable, if the fine type of student now in school and hospital is maintained. Our last word on the Bart.'s week must be of these students—for it is with the future as well as the past that we are concerned. Their demeanour during this trying week must have given pride to those elder brothers of theirs who now have charge of their medical education and welfare. Control and discipline were relaxed, study was impossible, and excitement and festivity were the order of the day. Yet there was no discreditable episode, and the utmost courtesy and consideration were shown to guests. In the hands of the present members of staff and the exceptionally fine type of student who is attracted to this school the tradition of Bart.'s is safe.

Annotations.

"Ne quid nimis."

DEFATTED BACTERIAL VACCINES.

THE valuation of vaccine therapy varies widely with the experience, enthusiasm, and prejudice of different observers. Everyone agrees that it has proved rather less encouraging than was at one time expected, and it is only those with some solid faith in the principles of immunology that have remained steadfast in their belief that with further knowledge of technique this method of preventing and curing infectious disease would come into its own. Preventive inoculation against tuberculosis has been almost or quite a failure, curative inoculation has not been any great success, and it is in connexion with this infection that the new work of Prof. G. Dreyer¹ will be studied with most interest. On the whole, he points out, anti-bacterial, as distinct from antitoxic, immunity can be achieved experimentally better with Gram-negative than with Gram-positive organisms, which suggests that the lipoidal substances, on which he believes Gram-staining to depend, are responsible for the failure of Gram-positive and acid-fast bacilli to arouse an effective response in the body. He shows that if the tubercle bacillus be first treated with formalin and then extracted with acetone, a thin writh of the body of the bacillus remains which is not acid-fast, is more or less easily digested with trypsin, and will cause the production of various antibodies when inoculated into animals. It will be remembered that Deycke and Much have claimed results from so-called partial antigens prepared on different lines. Prof. Dreyer further shows that repeated small doses of his preparation bring about a definite improvement, both general and local, in animals infected with tuberculosis. The preliminary observations of Dr. A. C. Inman at Brompton and Drs. P. Fildes and G. T. Western at the London Hospital on the treatment of human cases are encouraging and show that Prof. Dreyer's antigen is at any rate not injurious. Similar defatted preparations have also been made with staphylococci, streptococci, and other organisms, and are under examination with promising results, the absence of any painful local reaction being especially noteworthy. Prof. Dreyer gave a lecture expounding this recent work to a critical audience at the Institute of Pathology and Research at St. Mary's Hospital on June 14th, whereafter doubtless many immunologists will attempt to repeat and expand his work. We hope that more ample experience will confirm the value of this new departure in vaccine therapy, which is at any rate one of the most interesting and hopeful ventures on the therapeutic side of immunology that we have been able to chronicle for some time.

THE DEVELOPMENT OF EXOTIC MEDICINE.

To students of exotic medicine there are two countries which have always possessed a peculiar fascination. From time immemorial India and China have been lands of mystery, and despite the penetrative keenness of Western science the mysterious veil in the case of China, at least, has been parted but a little way. Such glimpses as have appeared have served to whet curiosity. It appears that English and American medical men and methods have been received with least disfavour by the Chinese, and the standard work on the Diseases of China is the joint labour of Prof. W. H. Jefferys, M.D. Pennsylv., editor of the *China Medical Journal*, and Mr. J. L. Maxwell, M.D. Lond. Their large and comprehensive volume was, however, as the authors themselves pointed out, little more than a scraping of the surface, and the real solid work yet remains to be done. It is not, perhaps, so much in the realm of constitutional diseases as in that of infectious diseases that we may anticipate results. Scarcely ten

years ago China furnished us with one of our most fruitful opportunities for the study of pneumonic plague, and it is less than 20 years since Catto, contemporaneously with Katsurada, made the discovery of the Asiatic schistosome and added by no means the least of its laurels to the young school of tropical medicine with which he was associated. These, however, are but two instances which indicate that China is a storehouse of material of intrinsic medical interest. It is not to be expected that Western medicine will care to assimilate all that the East has to offer in the shape of formula, but in Madras Presidency at least, as our Indian correspondent writes, the indigenous system of medicine has been deemed worthy of an exhaustive report by the Government. Whatever the outcome of this report may be, Western medicine can at least make extremely serviceable use of the study of such natural phenomena as present themselves. The natural resources of China which arouse the curiosity of speculative industrial magnates are, no doubt, paralleled in the field of medical and especially parasitological research, where equally dazzling possibilities may present themselves. This is evidenced by an interesting little brochure which has just been published by the Presbyterian Mission Press in Shanghai. Emanating from the Peking Union Medical College it is the work of Dr. Carroll Faust, a distinguished graduate of one of America's best known helminthological schools. Dr. Faust, who is shortly visiting this country, has been wise in his policy of laying a solid general foundation for future specific work. The superlative work of individual British tropical pioneers has often met with strenuous official opposition, instead of the coöperation which leads to fruitful issues. The team principle in medical research, while possibly not of American origin, has been exploited most successfully by American workers, who realise that the most productive results, in medicine as in other fields, are likely to accrue from some system of coöperation and coöordinated work. Dr. Faust's little pamphlet bears the ambitious subtitle "A Syllabus for the Clinicians of China," and there is a salutary lesson in the fact that it should have been left to a non-medical zoologist to prepare such a useful and up-to-date summary.

MEDICAL HYDROLOGY.

THE short course of lectures and demonstrations, under the auspices of London University Extension Board, which has just been concluded, was the first of its kind in England, and was attended by more than 20 medical men. Lectures were delivered at the University of London by Drs. Buckley, Edgecombe, Fortescue Fox, Leonard Hill, and Waterhouse. A demonstration on the applications of heat and cold was given at the Medical Research Laboratories, and lecturettes on methods of treatment employed in military cases at the Ministry of Pensions Special Surgical Hospital at Shepherd's Bush, including a demonstration by Dr. Arthur Herbert on the preparation and uses of radioactive mud from New Zealand and on hyperthermal baths. A comprehensive programme was carried through at Harrogate, in which Drs. W. Bain, W. Brown, G. Holmes, Liddell, Miller, Pringle, Saberton, Solly and others took part, the various forms of treatment given at the Royal Baths being demonstrated and discussed. In his concluding lecture on the applications of hydrology to incipient and chronic disease at different periods of life, Dr. Fortescue Fox described the distinguishing character of British spas as compared with those of other countries. The climatic character of a spa, he said, affects the action of every kind of bath. At Strathpeffer the mean summer temperature is 12° F. less than in the valley of the Rhine, and equal to that of Leukerbad at 4500 feet. Harrogate and Buxton are 8° F. cooler than Nauheim or Aix-les-Bains, and possess the same temperature as Bormio, near the Stelvio Pass. The position of Britain on the north-westerly fringe of Europe and its incomparable coasts give to the constantly changing atmosphere of these islands a stimulating quality, analogous in

¹ Brit. Jour. of Experimental Pathology, vol. iv., 1923, p. 146.

its effects to those of the effervescing bath. British spas are therefore the most tonic in the world, and, if suitably utilised for preventive and curative treatment, are well adapted to the chronic ailments and infections of our own country, such as catarrh, tuberculosis, and rheumatism. Among modern methods requiring development at home, Dr. Fox specified the utilisation of the British eliminative waters, the employment of various forms of effervescing baths, and the external treatment of young subjects by salt waters. New knowledge had been acquired of the physical properties of various waters: the patient investigations of a few devoted workers, like Winternitz and his pupils, had borne much fruit; new light was constantly being shed by physiological discovery (to a large extent in England); and last, but not least, the systematic instruction that had been given for 20 years in continental countries, in the schools and at the spas, had resulted year by year in attracting to the study of waters and baths a group of scientific workers. These and other causes, Dr. Fox concluded, had transformed the position which this group of physical remedies occupied in our *materia medica*, and entitled them to an assured and essential place in the future.

REST OR EXERCISE IN THE TREATMENT OF PULMONARY TUBERCULOSIS?

ON June 4th there was a general meeting of that very live body, the Society of Superintendents of Tuberculosis Institutions, at 122, Harley-street, when a paper was read by Dr. E. E. Prest on the Treatment of Pulmonary Tuberculosis by Graduated Labour. The paper was a criticism of this treatment, and the Society had invited Dr. Marcus Paterson to reply. Other members joined in the discussion which followed, and it was remarkable in this that many, if not most, of the speakers had themselves suffered from pulmonary tuberculosis. It is not often that, at a medical meeting, the discussion of the treatment of a certain disease is conducted by its victims, and it would be desirable if this practice were to be more common than it is. It would, for example, be remarkably instructive if the subjects of venereal disease were to join in a debate on its suppression, although the organisers of such a debate might experience some difficulty in recruiting speakers. On the present occasion it was a significant fact that most of the speakers who pleaded for prolonged rest in the treatment of pulmonary tuberculosis had been perilously close to, or within the limits of, the third stage of the disease, while the advocates of exercise and graduated labour were for the most part able-bodied persons or ex-patients who had had but a fleeting, Turban-Gerhardt-first-stage taste of the disease. Indeed, the influence of pulmonary tuberculosis on the opinions of individual speakers was so characteristic that, as each person spoke, it was possible to form a comparatively accurate estimate of the extent to which he or she had suffered from tuberculosis. This grouping of the speakers naturally suggests that while exercise may be very beneficial to persons suffering only slightly from tuberculosis, and to others who are quite immune to it, rest is the most important remedy for those whose disease is advanced. One of the chief criticisms directed against graduated labour in sanatoriums was concerned with its educational effects. It was pointed out that the fitter the patient, the more graduated labour he was given, and that there was a serious risk of patients drawing the erroneous conclusion that, the harder the work they were set, the fitter they would become. At the present time, with sanatorium treatment lasting only three or four months, the most important rôle of the sanatorium is its educative work, and it would be deplorable if patients were to leave these institutions with the impression that rest is bad because they see the worst cases kept in bed and the earliest cases exercised. One of the speakers who dwelt on the educational functions of the sanatorium in this connexion, ventured the caustic suggestion that had

Dr. Paterson kept his first-stage patients in bed and set his third-stage patients to navvying, more of his old Frimley patients would be alive. For he would have taught his patients by practical demonstration that first-stage cases ultimately prosper on a regimen of prolonged rest, while there is nothing like excessive auto-inoculation for speeding the third-stage patient to his end. In summing up the chief points of this debate, both Dr. Paterson and Dr. S. Vere Pearson, the Society's President, remarked that the differences of the two camps were not perhaps as marked and irreconcilable as the opinions of the enthusiasts at either extreme might suggest. Both remedies have their legitimate sphere of usefulness, and, as Dr. Paterson insisted, whether a lung be rested by an artificial pneumothorax or exercised by navvies' work, careless technique and supervision may produce but a sorry caricature, stultifying intrinsically valuable methods. Dr. Pearson suggested that while rest was suitable during the stage of toxæmia, exercise might be beneficial when toxæmia had ceased. No objection was raised to this perfectly sound generalisation, but who can say when the toxæmia of tuberculosis has disappeared? It is surely one of the most difficult questions to answer, but in insisting on the superiority of the rectal method of taking the temperature over the oral and axillary methods, Dr. Prest pointed the way to the readiest method of distinguishing between active and inactive, toxæmic and non-toxæmic tuberculosis. Until such laboratory methods as the rate of precipitation of the erythrocytes, the Wildbolz auto-urine tests and others have proved themselves trustworthy, the physician would do well to use his clinical thermometer as the chief arbiter between complete rest and graduated exercise.

SUPPURATIVE THYROIDITIS OR LYMPHANGITIC ABSCESS?

IT has hitherto generally been taught that most suppurative conditions in the lower anterior triangle of the neck originate in the thyroid gland—i.e., begin as a thyroiditis. In the *Schweizerische medizinische Wochenschrift* for May 3rd, Prof. P. Clairmont, of the University Surgical Hospital in Zurich, throws out the suggestion that in many cases the thyroid has little or nothing to do with abscesses in this position, and that they are often due simply to inflammation in the lymphatic vessels in the triangular space bounded by the main blood-vessels of the neck as they run under the sterno-mastoid muscle, by the median portion of the omohyoid muscle, and by the middle line of the neck. He has recently observed three cases, the clinical picture of which was remarkably uniform and well-defined. In every case a unilateral swelling appeared at the anterior margin of the sterno-mastoid in the lower part of the neck. In two cases suppurative thyroiditis was diagnosed, and in the third it was suspected, before the operation. This showed the abscesses to be unconnected with the thyroid gland and to be situated between one lobe of the thyroid and the mid-fascia of the neck. Microscopic examination of the wall of one of these abscess cavities showed it to consist of granulation tissue, and within none of these abscess cavities were lymphatic glands found. This condition must be distinguished from diffuse phlegmon of the neck; the type of abscess to which Prof. Clairmont refers is, indeed, well defined anatomically. The prognosis is as good as for lymphangitic abscesses in the limbs, and after free escape of the pus has been provided by incision, the temperature usually falls rapidly to normal, and uneventful recovery follows. One of the cases recorded was that of a lad, aged 16, who experienced a stabbing pain in the right side of the throat while eating blackberries. A few days later severe pain and dysphagia set in, and he could swallow fluids only with difficulty. A swelling in the neck under the jaw extended downwards, the temperature rose to 39.6° C., and he could neither speak nor swallow. Later a diffuse swelling appeared in the right, lower, anterior triangle of the neck, being

bounded by the middle line, the right clavicle, and a point three finger-breadths above the right clavicle. Deep fluctuation was demonstrable, and incision of the swelling under a general anæsthetic yielded much offensive pus, which oozed out from under the sternomastoid muscle. The pus contained the *Streptococcus pyogenes*. The abscess cavity was as large as a hen's egg and was situated between the right lateral lobe of the thyroid and the mid-cervical fascia. The patient made a slow but uneventful recovery. In distinguishing between this condition and suppurative thyroiditis more help may, in Prof. Clairmont's opinion, be obtained from the history of the case than from the local examination before operation.

APPARATUS FOR HYDROCYANIC FUMIGATION.

THE fumigation of ships by hydrocyanic acid gas has been enthusiastically advocated and practised by the United States port health authorities, but the occurrence in America and in England of fatal accidents during the process has hitherto prevented the universal adoption of the method. Dr. G. R. Seager Thomas sets out in our present issue the post-mortem findings in two fatal cases which occurred last July at Southampton as an instalment of a more complete report. In the current number of the *Journal of Hygiene* Lieut.-Colonel W. Glen Liston, I.M.S., and Mr. S. N. Goré compare the results of fumigation with HCN gas in a series of experiments on a ship using alternately the "dumping fixture" and Liston's "cyanide fumigator." The characteristics of these two forms of apparatus may first be briefly described.

The dumping fixture has been employed extensively in the United States. It consists of a barrel, to the upper edge of which one or two boxes are fixed on hinges. The barrel serves to hold a strong solution of H_2SO_4 , while the boxes are filled with NaCN. The contents of the boxes can be tilted into the acid when desired by drawing upon cords adjusted for the purpose. The HCN gas is generated in this way. No special arrangement is made to distribute the gas, and the quantity evolved depends on the quantity and quality of the NaCN used. The concentration of the poison gas present in the space under treatment is not estimated at any stage in the process, and no means are provided for getting rid of the poison after it has accomplished its work other than the natural ventilation existing on the ship.

Liston's cyanide fumigator is a more elaborate apparatus. The gas is generated in a closed box which can be placed in the open air. On the lid of the box a petrol motor, a fan, and a chemical cabinet are fixed. The motor is capable of revolving the fan at a speed of 3600 revolutions per minute, and at this speed it can draw into the generating box, through an inlet pipe six inches in diameter, and deliver through an outlet pipe of the same diameter, 1200 cubic feet of air per minute at a pressure of six inches on a water gauge. The apparatus and chemicals required for generating, measuring, and testing the poison gas are contained in the chemical cabinet. The gas is evolved within the generating box by allowing a solution of sodium cyanide to mix with a solution of sulphuric acid on a mixing platform within the box. The quantity of poison gas evolved is regulated by the rate of flow of the two liquids upon the mixing platform; this rate is controlled by two screw clamps fixed on the rubber tubing which conducts the fluids from the vessels in the chemical cabinet into the generating box. When the motor is working the poison gas is diluted as rapidly as it is generated with air drawn by the fan from the compartment under treatment through the inlet pipe connecting the generating box with the compartment. The poison gas, diluted in this way, is at once blown back by the fan along an outlet pipe connecting the fan and generating box with the compartment. The outlet pipe extends into the compartment for a considerable distance; it is furnished with a number of branches of gradually decreasing diameter, so that the diluted gas is carried to the remotest parts of the compartment and delivered there at from eight to ten different points. These points may be selected on the various decks of the ship. The air and poison gas within the compartment are thus continuously circulated through the generating box, where more poison gas can be added at will up to the concentration required to destroy rats, bugs, fleas, or other vermin. The concentration of poison gas in the air circulating through the machine can be estimated at any time by stopping the generation of the gas for a few minutes, while a measured volume of the air mixed with poison gas is

taken either from the outlet pipe from the fan, or, by making special arrangements, from any part of the compartment under treatment. The apparatus and chemicals for this purpose are provided in the chemical cabinet fixed to the machine.

Liston's fumigator thus differs from the dumping fixture in that (1) the poison gas, on generation, is rapidly diluted with air, so that high concentrations are avoided; (2) the evolution of the gas is constantly under control during the whole period of fumigation; (3) the concentration of gas within the room can be estimated at any time; (4) the distribution of gas in the compartment is rendered more rapid and even by mechanical means; (5) the gas can be displaced by fresh air when its work is accomplished, a system of artificial ventilation assisting the natural ventilation of the ship. The machines are portable and can be carried by two men. Each is equipped to deal with 60,000 cubic feet of space at one time, so that a number of machines or units are required for the fumigation of a ship; the units should be used simultaneously, so that the whole ship is fumigated at one time. The period required for completing the process is from three to four hours. A port health officer should be provided with at least ten units or machines.

The experiments detailed by the authors in their paper demonstrate the defects and dangers of the dumping fixture and the advantages, noted above, which are to be derived from the use of the fumigator. For instance, while 7 lb. of sodium cyanide scarcely sufficed to kill all rats when the dumping fixture was employed, 6 lb. were sufficient to kill all rats with the fumigator. The use of the fumigator probably ensures greater safety, first because the poison gas is generated in the open air, secondly because its rapid dilution prevents the occurrence of pockets of poison gas in high concentrations. With the fumigator economy in the use of cyanide and acid effects a saving which goes far to cover the greater primary outlay and running expenses, as against the smaller cost and maintenance charges of the dumping fixture. On the grounds of safety and efficiency, therefore, it seems possible that Liston's cyanide fumigator may replace the dumping fixture in the fumigation of ships by hydrocyanic acid gas. The publication of the complete report on the Southampton cases will be awaited with interest.

ARSENOBENZOL AND THE SPIROCHÆTE.

AN excellent survey of the position of arsenobenzol in the treatment of syphilis is contributed by Mr. Claude H. Mills to the April and May numbers of the *British Journal of Dermatology and Syphilis*. After considering the various methods of administering the drug and the points in its favour, the author discusses the limitations of the arsenobenzols in syphilis. He points out that the failure of arsenobenzol to cure cases of syphilis, in which some time has been allowed to elapse before treatment has commenced, is due to the fact that the *Spirochaeta pallida* has a power of remaining latent in avascular retreats where arsenobenzol is unable to reach it. No matter what drugs may supersede those in present use, they will be faced with the same problem of penetration. Another important point upon which the author dwells is the variation with which individual cases presenting a clinical similarity with regard to duration of infection respond to a uniform course of arsenobenzol treatment. It is probable that the rate of excretion exerts an important influence, for, as Mr. Mills points out, the patient who eliminates a given dosage slowly does better clinically than a patient who excretes the same rapidly, although at the same time he is more likely to develop such collateral effects as dermatitis and jaundice. The slower he excretes the greater the chance of a large proportion of the injected dose being converted into spirochæticidal derivative. Another point on which the paper lays emphasis is the dangerous nature of the relapses met with in cases that have been insufficiently treated with arsenobenzol. These relapses

are dangerous, the writer points out, not only from the patient's point of view, but sociologically, on account of the highly infectious nature of the surface lesions prone to develop at a date considerably later than in cases treated purely with mercury—or, in fact, in which no treatment at all had been received. Mr. Mills has seen such lesions as moist papules, mucous patches, and condylomata develop as relapses in patients as late as six years from commencement of arsenobenzol treatment in primary and secondary cases. The possibility of the occurrence of such delayed and highly infectious clinical relapses emphasises the importance of keeping patients under regular and prolonged observation wherever arsenobenzols are employed in the treatment of syphilis.

H.R.H. PRINCESS CHRISTIAN.

By the death of H.R.H. Princess Christian on June 2nd many good causes have lost a devoted friend. The nursing profession in particular had reason to be grateful for constant and influential assistance; Princess Christian was the founder of the Army Nursing Reserve, which was recognised by the War Office in 1897, and during both the South African War and the war of 1914–18 she was prominently associated with Red Cross work. As President of the Royal Free Hospital, and president or patron of numerous other hospitals and charitable institutions, Princess Christian displayed publicly the interest in national health which found private expression in the establishment and maintenance of a nursing home at Windsor (founded in memory of her son, Prince Christian Victor, who died at Pretoria in 1900), of a creche in the same town, and of a holiday home for crippled boys at Englefield Green. Princess Christian was for many years President of the College of Ambulance, and yet another of her interests was the work of the Home for British Lepers. She was a truly charitable lady, and the medical profession sympathise with the Royal Family in her loss.

CANCER IN PLANTS.

THE exhaustive researches of Dr. Erwin F. Smith, of Washington, on experimental crown-gall in plants¹ have led him repeatedly to emphasise the resemblances between the abnormal growths produced by *Bacterium tumefaciens* and malignant tumours in man. In his view, which is supported by Jensen, the bacteria start an irregular proliferation of the plant cells, which, without further stimulation, proceed to permeate the normal tissues and give rise to secondary tumours at a distance, partly from themselves and partly by inducing similar abnormal growth in the cells with which they are in contact. The facts have lately been re-examined by Messrs. Robinson and Walken in Manchester,² and the new observations which they have made show that Smith's interpretation is hardly tenable. In the original gall the bacteria are mostly present on the rough external surface, and the later development of the gall is for the most part due to their presence there. But the authors have succeeded in definitely demonstrating that the causative organisms also spread inwards in zoogloal strands along intercellular spaces and protoxylem vessels, and in this way form centres of abnormal growth and gall-production along their track. The primary and secondary galls and tumour strands arise by proliferation of pre-existing cells of the host in the presence of bacteria, and they find no evidence of invasive growth of tumour tissue or of the formation of tumours at a distance from the organisms. These observations appear entirely to invalidate the analogy which Smith has drawn between crown-gall and malignant tumours, one essential characteristic of which is that, once the abnormal growth has been started, it continues indefinitely without any further causative stimulus.

INTRASPINAL INJECTIONS OF ANTITOXIN IN MALIGNANT DIPHTHERIA.

THE intraspinal injection of antitoxin in diphtheria has hitherto been employed by only a few clinicians, and chiefly as a prophylactic or curative method of the paralytic sequelæ. Dr. E. Benhamou and his internes MM. Camatte and Flogny,¹ of Algiers, now recommend its use during the acute stage of malignant diphtheria, in which the child remains in a state of profound toxæmia, in spite of large doses of serum administered intramuscularly or subcutaneously associated with adrenalin, strychnine, or digitalis. In all the writers' cases in which the serum was given intraspinally, provided the injection was not given too late, a "veritable resurrection" was witnessed. It is most important not to wait too long before resorting to this method. If after the first 24 hours large doses of serum intramuscularly have not improved the condition, or if from the first the case seems desperate, 20–30 c.cm. of serum should be injected intraspinally after removal of about an equal quantity of cerebro-spinal fluid. Intramuscular injections of 20–40 c.cm. and subcutaneous injections of 40–60 c.cm. should also be given, and the intensive treatment should be continued subcutaneously during the following days. No bad effects such as anaphylaxis were ever observed after intraspinal injection. The method is not suitable for mild or moderate cases, which are readily cured by subcutaneous or intramuscular injection, but should be reserved for malignant cases.

Dr. Georges Dreyer, F.R.S., professor of pathology in the University of Oxford, has been appointed a member of the Medical Research Council in the vacancy caused by the resignation of Major-General Sir William Leishman, F.R.S., consequent on his appointment as Director-General, Army Medical Services.

As the result of recent conferences of the Presidents of various sections of the Royal Society of Medicine, a number of subjects have been decided upon for debate during the session 1923–24. The whole Society will be asked to discuss three important subjects: (1) The possible substitutes for cocaine; (2) the grading of the population from the point of view of bodily fitness; (3) chronic abdominal pain in nervous women. A further announcement will be made on the Diary cards.

THE Scottish Board of Health have appointed a Departmental Committee to inquire into the incidence of puerperal morbidity and mortality, with special reference to the causes contributing thereto, and to suggest any remedial measures. The composition of the Committee is as follows: Lord Salvesen, chairman; Mrs. Mary Barbour, a member of Glasgow Town Council; Dr. R. C. Buist, hon. secretary, Dundee branch of British Medical Association; Miss M. E. Cairns, vice-president, Scottish Midwives Association; Dr. T. F. Dewar, Scottish Board of Health; Miss A. M. Fraser, superintendent, Motherwell and District Nursing Association; Dr. Matthew Hay, a director of Aberdeen Maternity Hospital; Prof. B. P. Watson, professor of midwifery and gynaecology, University of Edinburgh; with Mr. C. L. Farmer, Scottish Board of Health, as secretary.

¹ Paris Médical, April 28th, 1923.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—The annual general meeting will be held at 11, Chandos-street, London, W., on June 21st, preceded by a Demonstration from 7.45 to 8.15, when (a) Dr. L. F. Hirst will show microscope specimens; (b) Col. Clayton Lane will show an ordinary centrifuge with buckets adapted for direct centrifugal flotation for use in the diagnosis of ankylostome infestation. The chair will be taken at 8.15 by Sir James Cantlie (retiring President). The first awards will be made of the Chalmers Memorial Medal and of the Manson Medal. Dr. L. Fabian Hirst, of Ceylon, will read a paper on the Spread of Plague in the East Indies (illustrated by lantern slides).

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXIV.

TREATMENT OF HÆMORRHOIDS.

Symptomatology.—The patient always appears with a ready-made diagnosis, but the medical man must be on his guard. In a patient of about 50, who has been only lately affected, malignant disease of the rectum is more probable than hæmorrhoids, which postulate a long-standing condition. The cardinal symptoms are: (1) hæmorrhage, (2) protrusion, (3) pain or pruritus. By far the most common, and often the unique symptom is hæmorrhage. It may be trifling in amount—a streak of blood noticed only in the stools—or the quantity may be large and the blood then escapes from the anus at any time, not only on defecation. Protrusion is a later phenomenon. It occurs where the vicious circle—piles, constipation, straining, larger piles—has progressed for some little time. Eventually, the piles are large enough to produce the reflex of a foreign body, and the pile-bearing area is extruded through the anal orifice on defecation. An acute complication of this process is strangulation of the pile area by the external sphincter. The consequence of repeated protrusion is congestion and trauma of the mass, leading to fibrous tissue formation or partial thrombosis and progressive enlargement and hardening of the hæmorrhoids. Each further protrusion facilitates a subsequent accident and finally a definite prolapse is produced.

If pain be the chief complaint the condition is probably not one of hæmorrhoids. In piles pain is a late symptom associated with strangulation or ulceration of a protruding mass. In so-called external piles pain is, of course, the only and urgent symptom. Other symptoms include a sensation of weight and dragging in the anal canal or sacral region. Pruritus indicates septic irritation or ulceration. Neuroses of various kinds may be noted in susceptible individuals.

General Examination.—The pulse is examined for high tension, the heart for valvular lesions, and the abdomen for enlargement of liver or spleen, tumours of large intestine, or fecal accumulations in the colon. A nodule of malignant disease may be found in the liver or the anterior abdominal wall before iliac glands are obviously enlarged.

Local inspection will exclude syphilis, gonorrhœa, fistula, and fissure. A tag of skin representing an obsolete extruded pile is strong evidence of present internal hæmorrhoids. A speculum—the short fenestrated Lockhart-Mummery pattern is the best—should be passed. The pile masses or ridges will fall into view through the fenestra, and their exact position should be noted. A condition occasionally noted in the absence of definite piles is the red, soft, velvety appearance of the anal mucous membrane, which bleeds readily. This affection is usually consequent on dysentery, and is not amenable to operative treatment. The finger may be used finally, especially if no piles are visible, to exclude new growth of the rectum or of the ilio-pelvic colon.

The diagnosis of piles being established, appropriate treatment becomes the main concern.

Treatment of External Piles.

The expression "external piles" signifies a hæmatoma from rupture of a vein of the anal margin. The patient is probably right in attributing his malady to a sudden strain or effort. Clinically the condition is one of a rounded bluish prominence at the anal orifice. It is always exquisitely tender; soft at first, harder as thrombosis progresses. Gas or a local anæsthetic should be given at once, and the apical third of the swelling snipped off with sharp scissors. Instant relief of pain follows. Under a dressing of 1 in 40–60 carbolic lotion the wound soon heals.

Palliative Treatment of Internal Piles.

If the hæmorrhoids have once appeared through the anal orifice local palliative treatment is rarely sufficient. In slighter cases this is worthy of trial, and in any event the patient generally demands non-radical measures in the first instance. Treatment consists in rest, if possible a week in bed, diet, laxatives, and local and internal medication. Diet should be restricted to milk only for the first two days, supplemented afterwards with bread, butter, milk-puddings, and later jelly, fish, and tripe. Eggs are inadvisable. The best laxative is a good teaspoonful of sulphur sublim., given in milk in the evening. If insufficient, pulv. glycyrr. co. may be added. Some patients do better on pulv. rhei co., gr. xx. To anæmic and nervous patients it is advisable to give iron and strychnine, and where there is cardiac insufficiency tr. digital., ℥v. A suppository once or twice a day is helpful; if hæmorrhage is free, ac. tannic., gr. v.; ext. hippocastani sicc., gr. ½; basis, ad circ. gr. xv.; if irritation and discomfort is the main symptom, ext. bellad., gr. ½; ext. hamamel., ℥x.; basis, ad circ. gr. xv., should be given.

In *ambulant cases* the diet cannot be restricted to the same extent. An ointment of the same proportions as the suppositories may be dispensed in a collapsible tube to which a rectal pipe is attached. Ext. hippocastani liq. 5 per cent., gtt. v.–x., b.i.d., a.c., may be prescribed. The ambulant patient should be instructed to wipe clean after defecation the protrusion of mucous membrane, not with dry paper, but with soft paper previously dipped into cold or tepid water. This detail makes a great difference to his comfort at least.

Radical Treatment of Internal Piles.

Contra-indications for radical treatment are: (a) permanent venous stasis due to liver and heart affections; (b) post-dysenteric capillary piles.

Indications are: failure of palliative treatment, considerable hæmorrhage, protrusion, and strangulation. The method to be selected depends upon the surgeon's personal bias. The procedures in actual use are: clamp and cautery, ligation, modified excision, and injection. To my mind, ligation or modified excision are the methods of choice.

The *clamp and cautery* should be restricted to the case of strangulated piles, where it is employed as an urgent measure by some of the best authorities. Others wait until sepsis and sloughing have subsided, and proceed as in non-urgent cases.

Injection.—I consider this procedure to be contra-indicated in large, multiple, readily-bleeding or prolapsing piles. Its use should be restricted to such cases as present a single pile mass which causes no great trouble except for its occasional escape from the anal orifice. It may also be selected when a general anæsthetic is contra-indicated. This method appeals to the patient because he need not remain quiet more than 24 hours, and because no general anæsthetic is required. The method consists in the injection of 20 per cent. ac. carbol. in glycerine aq. dest. aa, by means of a dental or a similar syringe. Four to six minims of this solution are injected through the base of the pile into its centre. One pile only should be treated at a sitting. Probably two injections will suffice to thrombose any one pile. If too much is injected, sloughing and sepsis may ensue with considerable pain, to say nothing of the risk of septic thrombosis. When the thrombotic process is complete the pile remains represented by a fibrotic ridge or nodule which causes no inconvenience.

Ligation gives very satisfactory results, especially in pedunculated or isolated pile masses. It consists in the reflection of the mucous membrane of the base of the pile, transfixion of the exposed fibro-vascular pedicle by a needle carrying a catgut ligature, and the ligation of the transfixed tissues. When the ligature is securely tied the pile is removed with scissors, leaving a stump to prevent slipping of the ligature.

Modified Excision.—A combination of excision, ligature, and suture is the method usually employed

in my practice. The patient lives on milk diet mainly for a week before operation, taking evening doses of sulphur subl. or of pulv. glycyrrh. co. If possible, the last two days are spent in bed on a diet of milk alone, an ounce of ol. ricin. being administered at night, and a large simple enema next morning and evening. A "binding" dose of opium and catechu is unnecessary if the diet has been adhered to. The patient is anaesthetised and placed in the lithotomy position and a wide area painted with iodine. The external sphincter is dilated slightly to allow of a thorough irrigation of the anal mucous membrane with warm normal saline.

It is sufficient to remove three, seldom four, of the largest piles, for the smaller piles disappear after operation. The proximal end of the pile ridge is marked by a pair of Spencer Wells forceps applied vertically to the surface; the pile ridge is then clamped firmly by applying a long Kocher pattern forceps to its base, horizontally to the surface, and in a direction radial to the anus, like the long hand of a clock. The pile ridge is then separated, along with the Spencer Wells forceps, flush with the upper border of the Kocher forceps, which remains grasping the base of the pile. The sections of thickened arterioles and venous spaces surrounded by fibrous tissue appear in the grasp of the forceps. A continuous suture of No. 1 catgut is applied by transfixing at intervals the base or pedicle by passing the needle between forceps and anal wall, and bringing the loops over superficial to the forceps. When this suture is drawn tight and tied it assures complete hæmostasis and approximation of the mucous membrane edges. The other piles are dealt with *seriatim*. The anal canal is carefully inspected for bleeding—the smallest degree of oozing must not be neglected—smeared with bipp, and the operation area is allowed to recede. Sterile gauze and T-bandage are applied and a $\frac{1}{4}$ -gr. morphine suppository is given. No tube is inserted.

After-Treatment.

Dressings.—Usually the replacement of the gauze pad applied on the table suffices. Protrusion may recur. A hot boric (or moss-bag) fomentation, backed by a rubber hot-water bottle, will relieve congestion, pain, and the prolapse, which should be smeared with sterile vaseline or soft bipp.

Diet.—Milk only for the first two days, thereafter milk diet; light diet after the first purgation.

Purgation is regarded as an ordeal by the patient, who is generally agreeably surprised after the event. Ol. ricin. 1 oz. is given on the third or fourth evening, depending on the abdominal flatulence, and pil. col. hyosc. gr. ii. on alternate evenings afterwards, unless the patient prefers senna or some other mild laxative.

Retention seldom occurs when the morphine suppository has been given; a hot fomentation to the perineum with a hot-water bottle on the hypogastrium is usually effective, or turning on the hands and knees.

Rest.—The patient remains in bed for ten days, in his room for 14 days, and should spare another week for convalescence if possible: total, 21 days.

Apart from the efficacy of this method of operation, it has subsidiary advantages. The patient may return to work in three weeks. The first evacuation after operation is less painful than after other procedures. As regards permanency of cure, the linear scars tend to draw up the slack mucous membrane and anchor it to the muscular wall, so that prolapse does not recur. After six months three or four linear radial scars can be seen; the smaller incipient piles have disappeared, owing probably to the slight tightening of the mucous membrane between the excised portions.

There are, of course, innumerable well-known methods of operation. I have confined these remarks to a method modified but slightly from that which during the war I found the most useful and speedy way of curing men sent to the base with piles.

Surgeon to Out-patients, French Hospital, London.

Special Articles.

THE PANEL CONFERENCE: REVISION OF THE TERMS OF SERVICE.

A SPECIAL conference of representatives of local medical and panel committees was held at the Central Hall, Westminster, on Thursday, June 7th, Dr. H. G. Dain, of Birmingham, presiding.

TERMS OF SERVICE FOR 1924.

Dr. H. B. Brackenbury, chairman of the Insurance Acts Committee (hereinafter called I.A.C.), proposed acceptance of the memorandum drawn up by the I.A.C. upon the revision of terms of service of insurance practitioners for 1924 onwards. This document, which contained the proposals made by the Ministry of Health, after consultation with the Approved Societies Consultative Council (hereinafter called A.S.C.C.), for the revision of the medical benefit regulations and the considered opinion of the I.A.C. thereon, had been previously circulated among panel committees for their approval and criticism. The memorandum, said Dr. Brackenbury, represented the deliberate policy of the I.A.C. for acceptance, or otherwise, as a whole by the conference. In drawing it up there had been two bodies of opinion to take into account. The first held that come what might the capitation fee for medical service under the Acts must be cut down at any cost. The second was more concerned to obtain from the doctors such improvements as would ensure a first-class service, and was then willing to back them up in the demand for any capitation fee which they could justify in return for such service. The I.A.C. had deliberately chosen to deal with the second body of opinion. Peculiar individual opinions had been ignored, ideas implying radical alteration in the basis of insurance practice had been ruled out, and there then remained to consider a number of suggestions, formidable enough, but not such as the doctors could not go a long way to meet. All the objections put forward by any substantial body of opinion had been duly weighed in the memorandum presented. There were, Dr. Brackenbury felt, three points essential to secure sympathy from the public: (1) Free choice of doctor, (2) limitation of panel lists, (3) re-statement in some general form of the range of service offered; and he advised the conference to do what they had to do generously and fully. Encouraged by a review of the financial position* prepared for the I.A.C. by an expert adviser, which included an investigation into the insurance fund as a whole, the I.A.C. was convinced that that fund contained a sufficient means to meet the reasonable demands of the medical profession without any Treasury grant at all. It was really one fund, although its division into a number of subsidiary funds and minor accounts had resulted in some confusion. He had himself no doubt that the large reserve accumulated was a result of the remarkable fall in incidence of incapacity, owing to a quite

* The conclusions reached in this review are as follow:—

1. The amount of the remuneration of the insurance practitioner, having been determined on its merits, must take its place as a charge against the National Health Insurance Fund with all other normal and necessary charges against that fund.
2. There is every indication that the National Health Insurance Fund is in a position of great strength to bear all such charges. The Government actuary, writing in March, 1922, on the results of the valuation of approved societies as at the end of 1918, said that "no student of social conditions can fail to be impressed by the financial strength of the system of National Health Insurance." The experience of years subsequent to 1918 must have confirmed that view.
3. The valuation of approved societies up to 1918 revealed profits of £17,000,000 over and above the amount of Contingencies Funds of £6,500,000, a total surplus of £23,500,000. The continued low sickness experience since that date gives a strong indication of further large profits on the valuation soon to be made.
4. The societies have made these profits over periods when large special grants from the Exchequer were supplementing the normal insurance funds, on the assumption—which experience

(Continued at foot of next column.)

justifiable miscalculation by the actuaries in 1911. This fall had been remarkable even in the larger approved societies, amongst which the incidence had never been more than 70 per cent. of what had been calculated, while in some of the smaller societies it had not exceeded 52 per cent. This was, Dr. Brackenbury added, in the main due to the treatment by panel practitioners of insured persons, and the immense reserve so built up ought to be considered part of the fund on which doctors had some claim. As a matter of fact, the moiety of this fund which was by statute invested by the Government for the societies had long borne only 3 per cent. and, since the war, 4 per cent. interest; but by a draft regulation issued during the last few days it was now to bear interest at $4\frac{1}{2}$ per cent. There was, in fact, no need to ask for a special Treasury grant, for if the medical service came forward with an offer to meet all legitimate criticisms and to offer a blameless service, this extra $\frac{1}{2}$ per cent. provided the necessary margin. The I.A.C. therefore proposed that discussion should in the first instance be directed to the alterations of the terms of service other than financial, any consideration of the amount of the capitation fee being postponed until the October conference.

After Dr. Brackenbury had thus spoken, the conference promptly agreed on the policy of accepting such alteration of the present terms of service as seemed good to the conference, "including a re-statement of the range of service to be included within the contract, with a view to securing for insured persons the fullest and best general practitioner service possible" with the proviso that the Ministry of Health should produce their complete scheme for 1924, including finance, not less than one month prior to the autumn conference to be held in September or October, in order that panel committees might place the actual situation before their constituents for consideration in time for report to that conference.

Waiting-room Accommodation and Lock-up Surgeries.

The I.A.C. expressed the opinion that an insurance committee would be right in seeing that proper and sufficient surgery and waiting-room accommodation was provided without necessarily waiting for a specific complaint with regard to a particular doctor from one of his insured patients, the co-operation of the panel committee being invited. In the matter of lock-up surgeries in urban areas, arrangements should be such as would enable a caller to get into personal touch with the doctor or his deputy with sufficient promptitude to meet the necessities of a case of emergency. This would entail either:—

(a) A resident caretaker and telephonic communication between the surgery and doctor's residence; or

(b) where the doctor lived within a distance limited in accordance with the decision of the Insurance Committee of the area, notice at the lock-up surgery visible day and night indicating where the doctor or his deputy would be found; or

(c) where the doctor lived at a distance so that only his deputy was available as a rule between certain hours, the giving of a written notice of the deputising arrangements to each of the doctor's patients.

(Continued from preceding column.)

of the working of the Act has not yet supported—that those funds were inadequate to meet the normal and necessary liabilities.

5. The favourable results, therefore, exceed any reasonable expectations which the societies could have entertained. The question of using these profits to any further extent to pay any part of the cost of medical benefit does not arise. But they are such as to enable the societies to face the future with confidence.

6. The other funds directly providing for benefits of insured persons—the Deposit Contributors' Fund and the Navy and Army Fund—are both in a very substantial position.

7. Behind the funds carried into the accounts of approved societies, there are substantial balances in the National Health Insurance Fund which make the position of that fund additionally secure. In the stamps sold account and the Central fund there were balances at the end of 1920 amounting to £5,500,000; and it seems not unlikely that the demands to be met out of these accounts will not materially have exceeded the amount of additions to the above balance, leaving that amount more or less intact at the end of 1923. The true financial position of the Reserve Suspense Fund will probably be difficult to estimate or some time to come, but it must, by its nature, be a potential source of great strength to the National Health Insurance Fund.

The conference accepted these standards without demur.

Limitation of Panel Lists.

The question of the maximum number of insured persons for whom a practitioner may accept liability is closely bound up with that of partners and assistants. Limitation had already been accepted in principle, and the I.A.C. recommended that no objection should be taken to reduction from 3000 to 2500 for a single-handed practitioner, and to 4000 for a practitioner with one permanent assistant. Representatives from industrial areas protested that, if such reduction was insisted on, not enough doctors could be induced to live in crowded districts, and that reduction would imply a premium on living out. It was alleged without contradiction that the large list men were often doing the best work, that all the complaints came from men with short lists, and that compulsory reduction would result in chronic patients being cut out of the doctor's list. One large insurance committee was quoted as having been converted from preference for a 1500–2000 list to approval of a 3000 list. A London representative urged with force that the insurance committee was there to see that the doctor did his work properly, not to interfere with the number of his patients. Exploitation of assistants as a commercial proposition was deprecated. Nevertheless the proposed reduction was accepted by a large majority, with the proviso that allowance up to the present maximum should be made for exceptional circumstances in existing practices.

Free Choice of Doctor.

Free choice between doctor and patient within the insurance service, up to the utmost limit possible, has always been contended for by the medical profession. The I.A.C.'s present proposal is to widen the present opportunity and to allow free choice by a panel patient at any time, coupled with the corresponding right for a practitioner to repudiate an insured person on his list. Such free choice would not affect the method of calculating remuneration. An amendment that no insured person should exercise his right of choice more than once in three months was lost. The conference agreed that free choice could be the more freely granted if the fear of canvassing could be removed, and an assurance was given from the chair that the Minister would take steps against any approved society official who canvassed. It was pointed out that in Manchester no friction had arisen from free choice, and that thus to put the insured person exactly in the position of the private patient did as a matter of experience greatly reduce complaints. The conference was emphatic in refusing to extend the privilege of change of doctor to patients taking their medical benefit from approved institutions, in view of the risk of patients being swept wholesale into such institutions which possessed powers with which the regulations could not deal.

Excessive Prescribing.

The A.S.C.C. having expressed some apprehension that the present system of checking excessive prescribing may discourage doctors from prescribing what is reasonably necessary, a revision of the system was proposed in an appendix to the I.A.C.'s memorandum. The gist of these proposals is that the function of investigation, whether or not a case arises for the panel committee to consider, should rest with the Ministry; that the question of whether there has been extravagance and how much should then be decided by the panel committee or, on appeal, by referees; that finally the question of the appropriate penalty should be considered by the insurance committee and decided by the Minister. Several areas in which the present system is now working well pleaded for its continuance. One large area, however, which had never yet been obliged to surcharge, saw the time coming when it might be forced to do so. Some mirth was excited by the naive

declaration of one delegate: "The present plan has worked perfectly; we have never surcharged anybody." The view of the I.A.C. on the matter was accepted.

RANGE OF SERVICE.

The A.S.C.C. had asked the Ministry of Health to confer with medical representatives as to possible amendments of the terms of service, with a view to facilitating the task of insurance committees in deciding whether particular services did or did not fall within the range of a practitioner's obligations. The I.A.C. agreed that it would be advantageous to attempt to re-state in some general way what the range of service should be understood to include, and had set out this re-statement in the form of two schedules, positive and negative.

Schedule "A."—Services included in the contract of an insurance practitioner:—

1. Such services as can in general be described as those which in the best interest of the patient can be performed by a general practitioner of competence and skill. These do not include services of a specialist character—viz., those set out in Schedule "B."

2. The provision for the administration of an anæsthetic in cases requiring it: (a) whenever the service is within the contract and is given within the provisions of the contract; (b) where the anæsthetic is administered by the insurance practitioner to a patient on his list for a service not included in the contract (except in the case of dental operations).

3. Assistance at an operation not within the contract where such assistance is given by the insurance practitioner of the patient.

4. Such other services, even though of a character such as those set out in Schedule "B," as, after an investigation of the individual case, are declared by the Local Medical Committee and the Insurance Committee of an area, or on appeal the Ministry of Health, to be within the contract.

Schedule "B."—Services not within the contract of an insurance practitioner include:—

1. Estimation of errors of refraction. Operations on the eyeball, lacrimal gland, or nasal duct.

2. Operations on the internal and middle ear. Operations within the nasal cavity and on the accessory sinuses. Tonsillectomy. Operations on the larynx and trachea (other than laryngotomy and tracheotomy).

3. Dental operations.

4. Major operations, such as: (a) Operations on the skull, brain, or spinal cord (other than lumbar puncture). (b) Removal of thyroid or lymphatic glands. (c) Removal of tumours of the breast. (d) Operations involving an opening of the thoracic or abdominal cavities (other than paracentesis thoracis or abdominis). (e) Operations on the urinary organs (other than suprapubic puncture and the passage of catheter or sound) and operations involving openings of the urethra. (f) Removal of internal piles. (g) Open operative treatment of fractures or dislocations. (h) Operations on the bones or joints or amputations other than those of the fingers and toes. (i) Plastic and orthopædic operations. (j) Operations on the arteries and veins (other than those required for the immediate arrest of hæmorrhage). (k) Amputation of the cervix uteri or removal of the testis. (l) Operations for excision of skin affections of a malignant nature or deemed to be malignant.

5. Treatment by X rays, radium, or electricity.

6. Such other services as, after investigation of the individual case, are declared by the Local Medical Committee and the Insurance Committee of an area or, on appeal, by the Ministry of Health, to be outside the contract.

Various amendments expressed the fear of extending the definition of "ordinary medical attendance and treatment," to include services not ordinarily given by the average medical practitioner. Dr. Brackenbury pointed out that the words in inverted commas did not occur in the Act and that the schedules were based on the simple principle that everything of a general practitioner kind should be within the service and everything of a specialist kind without the service. Obviously it would not be fair that every practitioner should be required to do for his insured person everything he was prepared to do for a private patient. The practitioner had a right to any specialty of his own. In certain rural areas an average might even include major operations. Definition of general practitioner service by exclusion was unavoidable, for definition by inclusion would run to volumes.

Anæsthetics, Lumbar Puncture, Vaccination.

An amendment:

That there is no justification for compelling an insurance practitioner to administer, without fee, an anæsthetic to a patient on his list for a service not included in the contract. led to considerable discussion and was lost after it had been pointed out that what was in question was the voluntary administration of an anæsthetic to his own patient and not at the dictation of the surgeon when, as was frequently the case, the latter chose the anæsthetist.

An amendment to delete the words "other than lumbar puncture" on Schedule "B" was defeated, on the general ground that any well-educated general practitioner should have this in his therapeutic equipment. A further amendment to add bacteriological and advanced biochemical examinations to the list of exclusions was withdrawn on the assurance that diagnosis came under another regulation. An amendment to have the obligation to perform vaccinations and other prophylactic injections removed from the duties of the panel practitioner was lost, the dilemma being brilliantly stated that prophylactic injections were not given by practitioners who did not believe in them, and must of necessity lighten the other work of those who did.

Requirements to be Satisfied by a Practitioner who Claims to Accept a Fee.

While no practitioner may accept from a patient whom he is under contract to treat any fee or remuneration for any treatment which is alleged to be outside the contract, the I.A.C. proposed that a fee might be asked for when two conditions are satisfied:—

(a) When the doctor prior to giving such treatment, or in case of urgency within two days after, furnishes the insurance committee on a form to be supplied by them for the purpose, with such particulars as they may require.

(b) When the doctor has satisfied the insurance committee, after consultation with the local medical committee, that he possesses one or other of the following qualifications: (1) Tenure of hospital or other appointments affording special opportunities for acquiring experience of the service rendered; (2) special academic or post-graduate study or recognised proficiency and experience in the particular capacity required for the service rendered; in each case combined with evidence of actual practice of the type of service rendered.

Of these conditions, the second—that of satisfying the local medical committee that the doctor is a specialist—is new. The practitioner who contends in effect "This is outside the service, and I propose doing it myself" must satisfy his colleagues of his capacity to do so. The new condition was accepted with general approval.

CERTIFICATES AND RECORDS.

The I.A.C. proposed to ask that the whole certification systems should be made more simple and elastic, especially with reference to (a) a reduction in the number of certificates to two or three instead of eight or nine; (b) a release from the obligation to give certificates to insured persons receiving treatment from some other person or institution. A motion to simplify certification in the direction of an omnibus form (one form for nine), accompanied by a practical illustration of how to do it, was gratefully accepted.

Disapproval was expressed of the use by the Stationery Office of the back of certification forms for advertising purposes, special objection being taken to the puffing of food preparations. It was decided to ask that proofs of any advertisement contemplated should be submitted to the medical service for approval, or as an alternative, that both sides of the form should be filled up with certification matter to the exclusion of advertisements. Any available space might, it was felt, be fairly used for the instruction of panel patients in their duties and privileges.

It was agreed to press for the removal, as in Scotland, of the compulsion to enter every item of attendance on the record card. A motion that clinical records only should be obligatory and that if and when other records were required they should

be obtained through panel committees from selected practitioners on payment, was lost by a bare majority.

COMPLAINTS AGAINST DOCTORS.

The I.A.C. proposed the giving to panel committees of more power and responsibility with regard to the efficiency of the service, amongst other things the power to take action with regard to practitioners who are not carrying out their terms of service. The A.S.C.C. had pointed out the occasional difficulty in securing effective consideration of the cases of panel doctors believed to be habitually so behaving that their continuance on the list was prejudicial to efficiency. The conference agreed to meet this difficulty. An amendment that it is inadvisable for panel committees to initiate complaints against doctors who are not carrying out their terms of service was rejected almost unanimously, and a motion was carried to the effect that the regulations should be tightened up for the removal from the panel of any practitioner who by consistent indifference to his duties endangered the good name of the panel service. The "indifference" referred to in this motion constitutes a new crime in the panel service. A representative of London agreed that while the panel committee was not yet in a position to take the whole of its disciplinary work in hand, yet a beginning should be made. In nine cases out of ten a word to the offender from the committee sufficed, in the small remainder of cases initiation of a complaint would be useful.

It was decided to press for the limitation of the period during which insurance committees can notify doctors against whom complaints are lodged. The conference felt strongly in regard to the working of the medical service subcommittees that the circulation should be prevented of statements irrelevant and frequently prejudicial to the cases before them. No practitioner or insured person should be required to answer any charge which had not been definitely formulated apart from any correspondence from which it appeared to rise. A proposal to get power for the chairman of this subcommittee to put witnesses on oath was regarded as impracticable.

SOME PROBLEMS OF ADMINISTRATION.

Rural Practice.—The memorandum of the I.A.C. considered that no settlement with the Government would be satisfactory which did not allow of special provision being made for certain rural practices with small panels. It was pointed out that the average mileage per visit might be two and a half or more, while the visiting rate was from two to six times as heavy in rural districts. In Devon an average panel was stated to be 500-600, and it was physically impossible to do more. It was, in fact, increasingly difficult in view of the rural depopulation for the practitioner to carry on and educate his children without some private means. A motion asking for further special compensation over and above the mileage allowance was accepted. Dr. J. P. Williams-Freeman set out the various proposals which had been made for assisting rural practitioners—additional grants, as in the Highlands; a minimum capitation list; a graduated capitation fee; increase of Poor-law salary; ordinary mileage loaded for distance; special grants on the basis of mileage units—difficulties had been experienced in putting any one of those into force and he supported the summoning of a meeting of representatives of rural areas to confer and take action. This was referred to the I.A.C. for its consideration.

Regional Medical Officers.—It was agreed that the I.A.C. should arrange with the Ministry of Health that no part-time medical officer should referee on the cases of any neighbouring practitioner.

Extension of Service to Diagnosis.—The conference expressed its unanimous opinion that at the earliest time, permitted by financial stress, there should be an extension of the medical service to matters beyond the general practitioner's range, that a beginning might be made with the provision of increased diagnostic facilities (X ray and laboratory), and that the relation-

ship of such extensions to present additional benefits should be carefully considered.

Efforts to Secure Unity.—A report was received on the question of coöperation between the Insurance Acts Committee and the Medical Practitioners' Union. The conference resolved to request its executive, within its present constitution and powers, to coöperate with any other medical organisations, so far as such coöperation would be advisable in the best interests of its work. It was decided to press for an increase in the direct representation of local medical and panel committees on the I.A.C. to the total number of 23.

National Insurance Defence Trust.—From the report of the trustees of this trust it appears that 80 per cent. of the total number of panel committees have actually subscribed to the fund, and another 9 per cent. have promised support. The fund stood at present at about £46,000.

Pensions Scheme.—With the assistance of several members of the London Panel Committee, a subcommittee had drawn up a report in which it was stated that no pensions scheme properly so-called was practicable, and that the only scheme fair to all participants would be one in the nature of deferred pay. Further, that no scheme of any kind would be likely to secure Government sanction unless supported by a great majority of insurance practitioners. It was pointed out in discussion that one-third of London practitioners were already over the age of 65 years and that most panel doctors preferred to invest the whole of their savings in their own way rather than have a deduction at the source for investment in trust funds bearing interest at only 4 per cent. A motion to inaugurate such a scheme of deferred pay was rejected almost with unanimity.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

IRISH MEDICAL ASSOCIATION.

The annual general meeting of the Irish Medical Association was held on June 6th. Senator W. O'Sullivan, of Killarney, was elected President, and Prof. F. C. Purser, of Dublin, Vice-President, for the ensuing year. Prof. R. J. Kinkead, of Galway, and Dr. Leonard Kidd, of Enniskillen, past presidents, were elected honorary members. The report of Council showed that the membership had declined in 1922, but the balance of the credit had increased from £255 5s. 1d. to £528 14s. 8d.

The President delivered an address dealing with the present position of public health and the curative system in Ireland. He said that the Irish Government had already given solid assurances of will and capacity to grapple with urgent social and economic conditions, but there was an almost total absence on the part of governments to request, or accept when given, the advice of the Irish medical profession on purely medical affairs. In the Free State there had been Commissions dealing with most questions of national importance *except* the health of the people. Many of the changes recently made in Poor-law administration had a great deal to recommend them, but so far as they included the medical services they had been decidedly for the worse. At the time these changes were being first contemplated their more serious defects were pointed out on behalf of the profession, but the warnings were unheeded, with the result that, at the present moment, the efficiency of the medical services, which were intended to meet the requirements of the less well-to-do classes, were at a lower standard than they had been for the past 25 years. In the modern sense there was no live public health service. The prevention of the spread of infectious disease was altogether dependent on the medical attendant who, in a large percentage of the cases, might be the dispensary doctor. For the latter office he received generally about £20 a year, which seemed to suggest that he was not expected to

take public health questions very seriously. The bad reputation of Irish sanitation was unfortunate from the commercial point of view for a food-exporting country. Commenting on the absence or inadequacy of medical inspection of school-children, of schemes of treatment for expectant and nursing mothers, and for the prevention and treatment of tuberculosis, he estimated that more than 50 per cent. of the entire Irish population received their medical treatment in the first instance from the dispensary doctors, numbering 800, who received altogether about £170,000. The mileage covered in doing this work, if charged at garage rates, would amount to something close on £500,000. From this it would be seen that it would pay dispensary doctors far better to run a garage and posting establishment than to undertake the medical treatment of the poor of their districts. If the main recommendations of the report of the Irish Public Health Council were adopted, they would secure, said Dr. O'Sullivan in conclusion, a reasonably adequate medical service for the Irish people, but the establishment of a Ministry of Health for Ireland was absolutely essential.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

THE PASTEUR CELEBRATIONS.

THE week of celebrations devoted to the memory of Pasteur gave rise to considerable interest throughout France, and especially in Paris and Strasburg. The reception at the Elysée on May 24th was attended by Members of both Chambers, by the Diplomatic Corps, the staff of the Pasteur Institute, the family of Pasteur, and members of the staff of all the principal hospitals of Paris. The unveiling of the magnificent bust of Pasteur, of which Mr. Aronson is the sculptor, was an impressive function. After those present had filed one by one in front of the new monument they repaired to the library of the Institute where Mr. Pasteur Valléry-Radot, son-in-law of Pasteur, welcomed them. The visit to the museum, where instruments and apparatus used by Pasteur were displayed, and to the crypt where he is buried, were no less impressive. A cantata was sung by girl students in the amphitheatre of the Sorbonne before the delegates presented their addresses, and great enthusiasm was manifested. The unveiling of plaques commemorating the place of meeting of Pasteur and Lister in 1892 and of the institution where the former pursued his earliest studies in Paris, took place on May 25th and 26th respectively, and subsequently at the Ecole Normale Supérieure Mr. Paul Dupuy read a hitherto unpublished letter written by Pasteur to the Minister of Public Instruction in 1862, outlining the broad scope of his proposed researches. Many other functions of importance were held in Paris over the week-end, after which the chief centre of interest was shifted to Strasburg. Here the President of the Republic inaugurated the monument erected to the glory of Pasteur, and later the Pasteur Museum and the International Hygiene Exhibition. This museum was founded by subscription, open to professors of bacteriology throughout the world; their response to an appeal was prompt and most generous. The exhibition will be open from June till October, and during this period many important congresses, notably one on diseases of the skin and one on experimental cancer, will be held there.

MEDICAL COUPONS: A SCANDAL AND AN INQUIRY.

The medical coupons scandal, which has been much discussed in French medical circles, has spread to the public and has caused widespread indignation. In order to make clear the basis of the trouble it is necessary to set forth the arrangements for the giving of medical care to those disabled in the war. Article 64 of the law concerning pensions indicates that the

State owes to all soldiers and sailors included in the said Act, throughout their life, medical, surgical, and pharmaceutical necessities in respect of the wound or illness contracted or aggravated in service for which the pension has been given. The pensioners have the right on demand to have their names inscribed on official lists made out each year at the town-hall of the place in which they reside. This inscription gives them a right to gratuitous care only for those accidents or complications arising out of the wound or the illness which has entitled them to a pension. Pensioners have the right of free choice of doctor or pharmacist, payment being made by the State on a tariff determined by law or by Statutory Orders.

The Machinery of the Act.

The way in which this service functions is as follows. The pensioner having duly inscribed his name on a special list receives a book of coupons, medical and pharmaceutical. This book contains 12 leaflets with counterfoils. If the pensioner needs attention he goes to a doctor or sends for him, according to the gravity of his indisposition, and the following procedure takes place: (a) the doctor writes his orders on the counterfoil of the book, which should remain in the hands of the sick man; (b) the doctor signs and detaches from the book the slip recording his visit, which slip will serve as a voucher for payment of his services by the prefect of the Department; (c) the doctor writes on another voucher the prescription which the pensioner should procure at the chemist's, and he signs this order; (d) the chemist in turn detaches from the book and signs this voucher, which will secure for him payment by the prefect.

Certain Abuses.

This book of medical and pharmaceutical coupons constitutes, in short, what is practically a book of cheques given by the State to the disabled. No cheque can be drawn out and presented for payment without the signature of a doctor. The result is that most of the abuses in using coupons delivered according to regulations cannot be committed without the complicity of a doctor. Certain dangers were obviously inherent in the presentation to all those entitled to gratuitous service of blank cheques on the Treasury, but the State had apparently thought it possible to adopt this procedure because of the confidence felt in the honour of the medical profession, who are alone able to make the cheques valid. There are unfortunately, however, in all professions certain individuals who cannot be trusted to withstand financial temptation. The Medical Syndicates, realising the danger of the procedure employed by the State, have frequently demanded the right to appoint certain doctors to superintend and control this service, but the State did not think it well to allow this intrusion into official administration. Unfortunately, official administration was powerless to prevent abuses. The scandal has been disclosed owing to a little mistake made by an employee of the town council of Marseilles. He had received a request for medical coupons from a representative of one of the societies for the disabled, but instead of sending the coupons to the representative himself, he had sent them to the individual pensioners whose names were inscribed on the book. These pensioners, astonished to receive a book of coupons without having demanded one, never having been ill and never having used any medical coupons, came in protest to the town-hall. This protest provoked an inquiry into the administrative control, which soon revealed the fact that certain doctors had abused their powers of signature and had misappropriated, or attempted to misappropriate, considerable sums, often with the complicity of pensioners and chemists. An official inquiry into the whole question is now actually in progress. Though it originated at Marseilles the scandal has spread to many districts in France, such as the suburbs of Paris, and has led to certain arrests. It is impossible to give a precise figure of the sum of which the State has been thus defrauded; the daily press has suggested

22 million francs in three years, but this is certainly an exaggeration. The scandal has led prominent medical men to deliberate what punishment should be meted out to those medical men guilty of misconduct not only professional but civil. It has been suggested that an *Ordre de Médecins* might be created, comparable to that of barristers or solicitors, imposing formal guarantees of honour. MM. Xavier Vallat, Léon Daudet, and Ambroise Rendu are bringing forward a Bill with this end in view. The proposed Order would be constituted in each district by doctors who had been in practice there for at least five years, and would sit as a Council of Discipline to investigate any complaints which might be addressed to them as to frauds committed by registered doctors or by their authorised agents. The Council would be able to impose various penalties, from a simple reprimand to a permanent interdiction from the practice of medicine. This question of the creation of an Order of Doctors is arousing great interest here, and I shall have occasion to return to the subject.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

THE INDIGENOUS SYSTEMS OF MEDICINE IN MADRAS PRESIDENCY.

The Committee appointed by the Madras Government to consider the question of the recognition and encouragement of the indigenous systems of medicine (Ayurvedic and Unani) in vogue in the Presidency have issued a voluminous report. The essence of the report is summed up in the following words used by the Committee: "From the standpoint of science the Indian systems are logical and scientific, . . . self-sufficient, efficient and economical" (except in the surgical line). They also are of opinion that only through the practice of these systems, under present circumstances, can the State hope to bring medical aid within easy reach of the mass of the people; it is, therefore, incumbent on the State to explore their possibilities to the full. With regard to medical registration, the Committee say that this is necessary in the interests of the public as well as that of the practitioner. The purpose of medical registration is only to discourage dishonest practice of any particular system; absolute prohibition of unregistered practice, as obtaining in many States of America, is not suitable for present conditions in India, and what should now be attempted is the securing of certain rights and privileges to the registered practitioner, as is done in the United Kingdom. The first step, however, should be the establishment of an adequate number of medical schools and colleges, from which a sufficient number of efficient practitioners might be sent out year by year. Registration for practitioners of the Indian system must, of course, be a separate and distinct register of indigenous practitioners. There must be no confusion on this point.

The Committee think it absolutely necessary to establish a new department of Indian medicine under the direction of a Commissioner, the policy of this new department being controlled and directed by a "General Council of Indian Medicine." The new department will obviously require a large number of practitioners trained in Indian medicine, who should be "fully self-sufficient and efficient to deal with both medical and surgical ailments." To attain this end the Committee think it necessary that "the Government should immediately establish colleges and schools, hospitals and dispensaries for the Indian systems of medicine," and if present financial stringency makes this impossible, they suggest that the existing centres of European medical education and medical relief should be made to subserve the interests of Indian medicine as well as European, "especially as it is highly desirable that students of Indian medicine should come into actual touch with the practice of Western methods, especially on the surgical side."

This provision would seem to lead to just the confusion it is necessary to avoid.

Administrative Development.

The administrative development of the Indian systems seems to have taken up a large part of the Committee's time and attention. They recommend that the first task of the Commissioner of Indian Medicine should be to organise (1) a Medical Administration Committee, (2) a Library and Text-book Committee, and (3) a Medical Education Committee. They also recommend that, to satisfy present conditions, two types of practitioners are required, with two standards of proficiency. Practitioners of the lower standard should be multiplied as rapidly as possible, and these men may be expected to settle down, or take up employment, in rural areas; whilst the higher standard practitioner would provide the high-grade general and consultant practitioner, and would be utilised in the fields of teaching and research. Suitable provisions should, however, be made for the lower-grade practitioner to qualify himself for the higher grade. This arbitrary creation of two grades of doctors must be held as retrograde. The whole development of the medical profession has progressed by pursuing the exactly opposite policy.

The Committee recognise the value of Western influences, for they recommend that "every scheme of study of Indian medicine, whether Ayurvedic, Siddha, or Unani, should make adequate provision not only for the efficient training in subjects appropriate to itself, but also for the teaching of the essentials of whatever is valuable in Western medicine—e.g., anatomy, physiology, surgery in all its branches, bacteriology, medical jurisprudence, including medical ethics, history of medicine, and so on." But if the Indian systems are ready to adopt modern developments and advances of Western medicine, would it not be better for them to join up at once with the Western system, bringing with them any drugs of value or any methods of treatment which are an improvement on those now in use in the Western system? Recent researches in the Calcutta School of Tropical Medicine have shown that some of the Indian drugs are not only effective, but are even more effective than some in the B.P. The Western system is always ready to adopt methods of treatment which satisfy scientific investigation, but it is opposed, and rightly so, to secret remedies, such as are passed down from father to son in the Indian indigenous systems.

A Suggested College of Indian Medicine.

The Committee recommend the establishment in Madras city of a central college of Indian medicine and an associated hospital. The cost of these institutions is to be wholly met from State funds, and the resources of laboratories, dissecting rooms, clinical teaching, &c., of existing institutions are to be made available, as far as possible, for the purposes of the new College of Indian Medicine. Approved institutions of Indian medicine maintained or established by local bodies and private agencies should be afforded State aid and such other forms of State encouragement as are accorded to similar institutions of Western medicine.

Finally, the Committee are of opinion that an Indian university may well be expected to interest itself in the promotion of Indian medicine by adopting such measures as the following: (1) Establishment of a University Chair of Indian Medicine; (2) provision for post-graduate lectures and courses; (3) establishment of a Faculty of Indian Medicine, with boards of studies, examination boards, &c.; (4) the founding of research scholarships and fellowships. They ask the Government to make a provision of five lakhs in their next year's budget for the promotion of Indian medicine.

The Committee's report has been published at the request of the Legislative Council, but it is probable that the Government will take some time to come to a decision on the different points raised in the report. Meantime it will be the subject of keen discussion by

all interested in medicine in this Presidency. It may be observed that more than one local body in the mofussil has already opened Ayurvedic dispensaries in place of those equipped according to Western ideas. Madras, May 15th.

UNITED STATES OF AMERICA. (FROM AN OCCASIONAL CORRESPONDENT.)

The Right to Prescribe.

THE right to prescribe was stoutly maintained by a decision in the Federal District Court of New York, given on May 8th. Judge John C. Knox ruled that Section 7, Title II. of the Volstead Act was unconstitutional in a suit brought by the Association for the Protection of Constitutional Rights. Section 7 limits the amount of alcohol in any form which a doctor may prescribe for any one patient to one pint in ten days. This limitation the judge regarded as arbitrary and without justification. Probably the intention of congress was not to restrict the prescription of necessary medicinal alcohol, but to prevent abuse of their privileges by dishonest physicians who might be tempted to issue prescriptions without any good professional reason. Medical men point out, however, that there is no limit placed on the amount of alcoholic liquor which a clergyman may order for sacramental purposes, and they consider that the profession of medicine is worthy of as much confidence as that of the Church. The prohibition authorities announce that regulations will not be relaxed until the decision has been reviewed in the Supreme Court. They are confident that it will then be reversed.

Automobile Fatalities in 1922.

The National Automobile Chamber of Commerce has just issued a statistical record of the automobile accidents which have occurred in 1922. The total number of deaths from this cause is 14,000, as compared with 12,500 in the previous year. The death-rate from this cause is thus still rising ominously. In the last three completed years it has been 0.104, 0.110, and 0.133 respectively per thousand population. The number of motor-cars registered per thousand population has in the same period increased from 87 to 115, so that the number of deaths per car has slightly decreased. It is interesting to note from the statistics on mortality among doctors collected by the American Medical Association that medical men run a much greater risk than the general population. The number of deaths from automobile accidents in 1922 was 39, and 23 more deaths were due to collisions between trains and motor-cars. The number of qualified physicians in the United States is estimated at 146,000, hence it appears that their mortality-rate from this cause is more than three times that of the general population.

Trudeau Sanatorium.

The thirty-eighth annual report of the Trudeau Sanatorium, just issued, is a mine of information for the statistician. The tables which it contains have been prepared according to suggestions made by the National Tuberculosis Association. One of them gives the present condition of all patients discharged in each year from the year 1885 onwards, the cases are divided into three classes (minimal, moderately advanced, and far advanced) with three subclasses in each class according to the condition at the time of discharge (apparently arrested, quiescent, and active). Of the patients discharged during the last year nearly one-fourth had no r les, about one-tenth lost their r les, in nearly one-tenth the r les remained unchanged. Fewer r les were heard at discharge than on admission in nearly one-fifth, and more extensive r les in nearly one-tenth. R les developed in new areas in about one-third. The X ray results were encouraging, showing clearing in no less than 150 out of 226 cases. Fifty of these cases had, however, an increase or

development of r les. Dr. Heise, commenting on the want of parallelism between clinical and X ray findings, suggests that "r les appear early in the stage of activity when inflammation is not too severe and reappear when the inflammation subsides and allows air to flow freely in the smaller bronchi and bronchioles in sufficient volume to set the mucus in vibration, or that increased secretion of mucus may take place before any X ray evidence." The special diagnostic criteria adopted will be of interest to sanatorium superintendents.

KING EDWARD'S FUND. SPECIAL GRANTS TO LONDON HOSPITALS.

WE published last week a brief report of the annual meeting of King Edward's Hospital Fund for London, and we now print the list of grants in connexion with the Combined Appeal. The question of hospital accommodation has a very important bearing on the position of the voluntary hospitals, and it is interesting to note that an Ambulances Cases Disposal Committee has been given the powers of the General Council "to inquire and report to the President and General Council on the methods at present employed for ascertaining where bed accommodation is available at hospitals in the metropolitan and neighbouring areas for accident cases requiring admission; and on the proposal that daily reports of vacant beds should be supplied to the police and ambulance authorities; and to make such consequential recommendations as they may consider desirable."

Distribution of Proceeds of Combined Appeal.

Approval was given to the special distribution by the King's Fund of the proceeds of the Combined Appeal. The hospitals to which grants are made are those which accepted the invitation to co operate in the appeal. Out of 127 invited to co operate 120 accepted.

Name of Hospital.	Total grant.
Acton Hospital	4585
All Saints' Hospital	875
Antivivisection Hospital	980
Baby Clinic and Hospital (Kensington)	360
Beckenham Cottage Hospital	630
Belgrave Hospital for Children	1,825
Blackheath and Charlton Hospital	525
Bolingbroke Hospital	1,200
Brentford Cottage Hospital	85
British Hospital for Mothers and Babies (Woolwich)	760
Cancer Hospital	1,820
Canning Town Women's Settlement Hospital	855
Central London Ophthalmic Hospital	925
Central London Throat and Ear Hospital	1,000
Chelsea Hospital for Women	1,130
Cheyne Hospital for Children	1,325
City of London Hospital for Diseases of the Heart and Lungs (Victoria Park)	4,275
City of London Maternity Hospital	1,540
Clapham Maternity Hospital	825
Dreadnought Hospital (Seamen's)	7,415
East End Mothers' Lying-in Home	1,130
East Ham Hospital	260
East London Hospital for Children	5,200
Elizabeth Garrett Anderson Hospital	2,830
Eltham and Mottingham Cottage Hospital	180
Evelina Hospital	1,910
Finchley Memorial Hospital	625
Florence Nightingale Hospital for Gentlewomen	665

TUBERCULOSIS.

Tuberculosis in Bradford.

THE Medical Research Council has issued as one of its Special Report Series an investigation by Dr. Harold Vallow of tuberculosis in insured persons accepted for treatment by the Bradford Health Committee. The period covered is July 15th, 1912, to April 30th, 1921, and a special study was made of the 584 cases of pulmonary tuberculosis applying for treatment in 1914-16. In addition, there were 20 cases of non-pulmonary tuberculosis. It was found that of the 204 patients in the first stage, only seven, or 3.4 per cent., had died from pulmonary tuberculosis, whereas of the 158 second-stage patients, 87, and of the 222 third-stage patients, 220 had died from pulmonary tuberculosis. The treatment given was sanatorium, hospital, and domiciliary treatment, but little information is vouchsafed as to the duration and character of the sanatorium and hospital treatment, and the character and extent of the domiciliary treatment given are not fully described. Apparently no distinction has been made between sputum-positive and sputum-negative cases, and owing to these and other important omissions, it is difficult to form an estimate of the value of the tuberculosis work in Bradford. It would be well if, in the preparation of reports of this kind, a uniform procedure were to be followed, so that a fair comparison could be made between the tuberculosis organisations in the various parts of the country.

The X Ray Diagnosis of Pulmonary Tuberculosis.

A small monograph¹ has recently been published by Dr. Max Cohn on this subject. A particularly interesting chapter is devoted to the X ray diagnosis of miliary tuberculosis, and of all the forms of pulmonary tuberculosis, the miliary is, according to Dr. Cohn, the one which presents the most definite X ray picture. The X ray diagnosis of miliary tubercle of the lungs is barely ten years old, but it has been worked up to such a pitch of perfection that this condition may now be detected by the X rays earlier than by any other method. Dr. Cohn supports this claim by an account of a soldier admitted to his hospital during the war for observation. There appeared to be little amiss with him apart from occasional attacks of lassitude; the ordinary physical chest signs were negative. But the X rays showed the characteristic fine mottling, and after six weeks the patient died, and the necropsy confirmed the X ray diagnosis of miliary tubercle. Again and again Dr. Cohn has diagnosed miliary tubercle of the lungs at a stage when the clinical diagnosis halted between influenza, empyema, and an interlobar effusion.

A Report on the Friedmann Vaccine.

The Committee appointed by the Prussian Landtag to inquire into the merits of the Friedmann vaccine has now issued its report.² It is not very helpful. This was, perhaps, inevitable. For as many members of the Committee had long ago ranged themselves on one or other side as inveterate enemies or enthusiastic advocates of the remedy, a unanimous report could hardly have been expected. The main report is a lukewarm analysis of the results achieved, and the nine members of the Committee not signing this report have dissociated themselves from it in two groups, the one insisting that the report is too favourable, the other too unfavourable. It would, therefore, seem that the result of the work of this Committee is to prove that the Friedmann remedy is useful, useless, neither, or both.

DURHAM MEDICAL GRADUATES ASSOCIATION.—The annual meeting will be held at the College of Medicine, Newcastle-upon-Tyne, on June 25th, at 5 P.M., and the annual dinner at 7.45 P.M. on the same day in the King's Hall, Armstrong College. Any Durham medical graduates who are not already members of the Association and who desire to join, are requested to communicate with the hon. secretary, (North), Royal Victoria Infirmary, Newcastle-upon-Tyne.

THE OCTOCENTENARY OF ST. BARTHOLOMEW'S HOSPITAL, 1123-1923.

THE proceedings in connexion with the Octocentenary of St. Bartholomew's Hospital began on Tuesday, June 5th, by a solemn service in the church of St. Bartholomew-the-Great, Smithfield, all that remains of the Priory of the Augustinian Canons Regular founded by Rahere in 1123. The address was given by the Bishop of Chester, a son of the late Sir James Paget whose life and work was so closely interwoven with St. Bartholomew's. The service was followed by a solemnity in the hospital square, Canons Regular of St. Augustine of 1923 commemorating with praise to God the Founding of St. Bartholomew's Priory by Canons Regular of St. Augustine of 1123. A herald, attended by Yeomen of the Guard, read the proclamation commanding, in the names of the Prince of Wales, President of the Hospital, the Lord Mayor and the Aldermen of London, and the treasurer and governors of the Hospital, that the celebrations should begin, and there followed a series of pageants representing episodes in the history of the hospital—the return of Rahere from his pilgrimage in Rome in 1123 and his meeting with Richard, Bishop of London; the presentation of the Charter by Henry VIII.; and hospital work in modern times.

On the same day the Prince of Wales received addresses in the Guildhall, London, from delegates from all parts of the world representing the Church, the universities of the Empire and the United States, and the learned societies of England, Scotland, and

PROCLAMATION.

BARTHOLOMEW FAIR,

June 6th, 7th, and 8th, 1923.

THE Right Honourable Edward Cecil Moore, Lord Mayor of the City of London, and his Right Worshipful Brethren the Aldermen of the said City, Straightly charge and command, on behalf of our Sovereign Lord the King, that all manner of persons of whatsoever estate, degree, or condition they be, having recourse to this Fair, keep the peace of our Sovereign Lord the King.

That no manner of persons make any congregations, conventicles, or affrays, by which the same peace may be broken or disturbed, upon pain of imprisonment and fine, to be made after the discretion of the Lord Mayor and Aldermen.

Also, that all manner of sellers of wine, ale, or beer sell by measures sealed, as by gallon, pottle, quart, and pint upon pain that will fall thereof.

And that no person sell any bread except it keep the assize and that it be good and wholesome for man's body upon pain that will fall thereof.

And that no manner of cook, pye baker, nor huckster sell nor put to sale any manner of victual, except it be good and wholesome for man's body upon pain that will fall thereof.

And that no manner of person buy nor sell but with true weights and measures, sealed according to the statute in that behalf made, upon pain that will fall thereof.

And that no manner of person or persons take upon him or them within this Fair to make any manner of arrest, attachment, summons, or execution, except it be done by the officers of this City thereunto assigned, upon pain that will fall thereof.

And that no person or persons whatsoever within the limits and bounds of this Fair presume to break the Lord's day, in selling, showing, or offering to sale, or in buying or offering to buy, any commodities whatsoever; or in sitting, tipping or drinking in any tavern, inn, alehouse, tipping-house, or cook's house; or in doing any other thing that may tend to the breach thereof, upon the pains and penalties contained in several Acts of Parliament, which will be severely inflicted upon the breakers thereof.

And finally, that what persons soever find themselves aggrieved, injured, or wronged by any manner of person in this Fair, that they come with their complaints before the stewards in this Fair assigned to hear and determine pleas, and they will minister to all parties justice, according to the law of this land and the custom of this City.

GOD SAVE THE KING.

It is his Lordship's pleasure that this Fair do finally end on Friday, 8th June, 1923, at Seven o'clock.

EDWARD C. MOORE, Lord Mayor.

Ireland. Lord Stanmore, treasurer of St. Bartholomew's Hospital, presented the Prince with a commemorative gold medal on behalf of the governors, which bore on the obverse the head of Rahere the founder, and on the reverse that of Harvey, the discoverer of the circulation of the blood, who was associated with the hospital as a physician from 1607 to 1643. After the Prince had presented commemorative medals to Lord Bearsted (for the Lord Mayor), to Lord Stanmore, and to Alderman Sir John Baddeley, chairman of the Octocentenary Grand Committee, congratulations were offered by the Bishop of Worcester on behalf of the Church, by Sir Archibald Garrod on behalf of the universities of the United Kingdom, by Dr. Alexander Primrose, of Toronto, for the Dominions and India, while Dr. W. H. Welch spoke in the name of the Rockefeller Institute,

Tableaux in the Great Hall.

On Wednesday, June 6th, and the following day a series of tableaux, illustrative of events in the history of the hospital, were shown in the great hall. They represented Rahere the Courtier; Rahere in a Dream Delivered from a Dragon by St. Bartholomew; the Building of the Hospital by Rahere; the Crowning of the Victor at a Tournament in Smithfield in 1422; a Girl Cured at the Tomb of Rahere; Henry VIII. giving the Deed of Covenant to the Lord Mayor at an Audience at Bridewell in the Presence of Prince Edward, afterwards King Edward VI.; King Charles I. and Harvey; Hogarth Painting the Pool of Bethesda; and Modern War Work. The most impressive picture was that of the venerable, austere, and yet kindly figure of St. Bartholomew protecting

St. Bartholomew's Hospital: the Future.

Sketch of one of the alternative plans for rebuilding the Ward Blocks, suggested by Mr. H. J. Waring and Mr. T. A. Lodge, A.R.I.B.A., in the "Short History."

and Sir Walter Fletcher on behalf of the learned societies of England. The Prince, in his reply, said that it was not impossible that a few aged men who had fought at the Battle of Hastings might have passed their last days in this old house of healing; from that period up to the present time, when Englishmen who fought in the latest and greatest of our wars had benefited by the knowledge gained at St. Bartholomew's, we could point with justifiable pride to a list of distinguished men, such as William Harvey, John Abernethy, John Radcliffe, and Percival Pott, who had been members of the staff.

Bartholomew Fair was opened by the Lord Mayor on June 6th in the presence of a large audience. The herald read aloud the proclamation given on the opposite page.

The fair was well attended every day—booths and side-shows proving hardly more attractive than the genial pranks of the lads in Tudor dress who, throwing aside all thoughts of studies for one glorious week, worked as hard in other directions.

the terrified Rahere from a dragon and claiming as his reward the building of a hospital dedicated to his name. All the tableaux were beautiful in conception and arrangement, and the appropriate music, contributed by the orchestra of the Royal Academy of Music, enhanced the pleasure given to the eye and ear.

In the afternoon there was a reception at the Royal College of Surgeons, the guests being received by Sir Anthony Bowlby, the President, and Sir D'Arcy Power, the Vice-President.

Old Students' Dinner.

The old students of the hospital dined together in the noble precincts of the Merchant Taylors' Hall on the evening of June 6th. Mr. H. J. Waring took the chair, and seated around him at the high table were a large number of the distinguished delegates attending the celebration from all parts of the United Kingdom and the Dominions. Mr. Waring, in proposing "The Hospital," referred to the three critical periods in its

history, the foundation by Rahere, the granting of the Charter by Henry VIII., and the decision 20 years ago to stay in the city. He mentioned the special needs of the immediate future as an extended obstetrical department and clinical laboratories attached to the wards. Whether the wards, which dated from 1730 to 1760, should themselves be rebuilt was still in suspense, but for himself he felt that their modernisation would be the thankless task of converting an out-of-date factory. Lord Stanmore, treasurer to the hospital, in responding, mentioned new sources of income which had been found, remarking, "This year we shall make both ends meet." The governors, he said, were unanimous that the voluntary system should be maintained and the hospital made fit for all requirements. A committee of five—two governors, two members of the medical staff, with the treasurer as chairman—had been empowered to choose plans and engage an architect. Sir William Lawrence, in proposing "The Medical College," mentioned the primary need for more operating theatres. He alluded to the very pleasant relations always existing between students and staff, and paid a tribute to the work of Dr. T. W. Shore, the Dean. Dr. Shore, in responding, alluded to the curious blend of ancient and very modern in the Medical College, which, as a separate chartered institution, was less than two years old. There was no record when students first attended, but certainly as early as 1662. Funds were wanted for a new residential college, for general endowment of the Medical College, and for research, besides the other objects named. Dr. H. Williamson proposed "The Guests," spiritual and temporal, in a brilliant and witty speech, and the toast was responded to by Lord Methuen, chairman of King's College Hospital Committee (delegate of the Bishop of Salisbury), Prof. T. K. Monro (delegate of the University of Glasgow), and Prof. W. H. Welch (delegate of the Rockefeller Institute). The last-named gave expression to the conviction that it is the teaching hospital that does the best by its patients.

Freemasonry: Rahere Lodge.

A meeting of this Lodge was held, in connexion with the celebrations, on Friday, June 8th, at the Freemasons' Hall, Great Queen-street, London, when some 350 members of the medical profession and their guests, including many Grand Officers, were present. H.R.H. the Duke of Connaught, Most Worshipful Grand Master, honoured the Lodge with his presence, and, on the motion of W.Bro. R. J. Reece, P.G.D., seconded by Sir D'Arcy Power, P.G.D., was elected an honorary member and was presented with the Lodge jewel. His Royal Highness, in thanking the members for the honour they had conferred upon him, recalled that the Rahere Lodge was consecrated by his brother, King Edward VII., when Prince of Wales, and expressed the hope that the Lodge would continue to flourish in the future as it had flourished in the past. On the motion of W.Bro. H. Morley Fletcher, P.G.D., seconded by W.Bro. Harold Pritchard, H.R.H. the Prince of Wales, P.G.W., was also elected an honorary member of the Lodge. During the evening Bro. Girling Ball was installed in the Master's chair by the M.W.Pro Grand Master, Lord Amptill, assisted by the retiring Master. The new Master invested his officers as follows: I.P.M., W.Bro. Harold Pritchard; S.W., Bro. Arnold Stott; J.W., Bro. Reginald M. Vick; Chaplain, Rev. R. Beaty Dand; Treasurer, W.Bro. Ernest Clarke, P.G.D.; Secretary, Bro. Geoffrey Evans; D.C., W.Bro. C. H. Perram, P.G.D.; S.D., Bro. H. D. Gillies; J.D., Bro. Langford Moore; Assist. D.C., W.Bro. H. Edmund G. Boyle, L.R.; Almoner, W.Bro. E. Laming Evans, L.R.; Organist, W.Bro. L. W. Bathurst, L.R.; Assist. Sec., Bro. T. H. Just; I.G., Bro. H. W. Henshaw; Senior Steward, W.Bro. E. P. Furber, P.P.G.J.W. Surrey; Stewards, Bros. I. de Burgh Daly and E. D. Whitehead Reid. The Rahere Lodge, which was founded by St. Bartholomew's men, was the first of the hospital lodges, of which there is now a good number, and it

must certainly be unique in the annals of private lodges for its Master to have been installed by the M.W. Pro Grand Master in the presence of nearly a hundred Grand Officers.

Obituary.

EDWARD JOHN STEEGMANN, O.B.E.,
M.B., B.S. DURH., D.P.H.

WE regret to announce the death of Dr. E. J. Steegmann, which took place at a nursing home in Leeds on June 8th.

Edward John Steegmann was born in October, 1867, and was the only son of Mr. E. Birkhead Steegmann, of Nottingham. After a school education, which was much interrupted by ill-health, Steegmann entered St. Mary's Hospital, whence he qualified M.R.C.S., L.R.C.P., and L.S.A. in 1892, and then proceeded to Durham, where he graduated in medicine and surgery in 1894, after acting as additional medical officer of health for the port of Newcastle during the period of cholera prevalence in 1892. Returning to London he became a house surgeon at St. Mary's Hospital and subsequently house physician at the Brompton Hospital, and then settled in private practice at Grove Park, Chiswick. His principal interests from the outset lay in the direction of public health work, for which he qualified himself by taking the D.P.H. in 1897, by becoming a member of Gray's Inn, where he was ultimately called as a barrister, and by teaching hygiene at St. Mary's Hospital and elsewhere. In 1901 he was appointed medical officer of health for the combined district of Heston, Hounslow, and Isleworth, a post which he held till 1909, together with that of medical officer of the Dockwell Small-pox Hospital. In this appointment Dr. Steegmann developed, with notable success, a variety of practical health measures which are now commonplace, but at that period were unusual. In 1901 also he undertook, at first concurrently with his work as medical officer of health, and later as a whole-time appointment, the arduous task of secretary to the Royal Commission on Human and Animal Tuberculosis. For ten years work was undertaken by the Commission on a scale quite without precedent in any Government-supported medical investigation in this country.

In all this period Dr. Steegmann was indefatigable as a manager and director of the Stansted research establishments and as interpreter of the decisions of the Commission. He was specially successful in securing for it the coöperation and interest of the Government departments concerned, and the effective presentment of the reports of the investigations. When the Commission terminated in 1911, Dr. Steegmann had good reason to anticipate that its scientific workers, together with the experimental farms and laboratories, would be taken over by the Local Government Board as an official research institute and the decision against the project caused him great disappointment. Between 1911 and 1914 he completed the final volumes of the Commission's reports and occupied himself with literary and other interests from his house at Isleworth, where he had a wide circle of friends. In 1914 he was called on at once for active service as a medical officer of the Royal Naval Volunteer Reserve; he went afloat in a hospital ship with the North Sea Fleet, and was with the Antwerp expeditionary force; subsequently he was transferred to the Mediterranean and served as surgeon respectively in the *Sir Thomas Picton* and the *Skirmisher*. In September, 1917, he was invalided home but was employed at the Admiralty, with the rank of Fleet-Surgeon, R.N.V.R., for special sanitary investigations. These included an investigation of the sanitary condition of Osborne College, and later a special mission, in relation to malaria, to Sierra Leone, Dakar, and other East African ports. Dr. Steegmann's work at the Admiralty, by the direction of Sir H.

Norman, the Director-General, was largely instrumental in bringing about the present system by which the Royal Naval Medical Service maintains specialist sanitary officers at the great naval seaports. A temporary appointment at the Ministry of Health, at the time of its creation, enabled Dr. Steegmann to take up a new interest—namely, the organisation for health purposes which it was then proposed to create at the League of Nations—and in 1921 his services were lent to the Geneva Office in order that preliminary measures might be organised to establish a health section of the League. Dr. Steegmann accepted this mission on condition only that he should not be considered as a candidate for any permanent medical post under the League, which he might decide to recommend, and at the end of the year, when the present medical director was appointed, he retired from this work.

For some years Dr. Steegmann had been handicapped by chronic ill-health, and the leisure at length obtained proved unhappily to be of short duration. He married in 1895, Mabel, daughter of Rear-Admiral Barnett, R.N., who died in 1914, and is survived by two sons.

GEORGE FREDERICK MURRELL, M.B. LOND., PHYSICIAN, ROYAL BERKSHIRE HOSPITAL.

THE death of Dr. G. F. Murrell at the age of 55 years after a brief illness, has been felt as a severe loss by the whole of Reading and the neighbourhood. Recently he had suffered from a carbuncle, from which he apparently recovered, and after a short change in the country resumed his work. It was obvious, however, that he was not well, and no doubt his resisting power had been severely diminished. At the end of May he developed cellulitis of the scalp of streptococcal nature, and the end came on June 5th with a virulent broncho-pneumonia and thrombosis of the cavernous sinus.

Born at Ealing, Dr. Murrell received his education at University College School and St. Bartholomew's Hospital. He qualified M.R.C.S., L.R.C.P. in 1890, and graduated M.B. Lond. in 1893. He subsequently held the posts of house surgeon at St. Bartholomew's Hospital, and house surgeon and house physician at West London Hospital. After serving as ship's surgeon on two occasions he settled in Reading in private practice in 1896, where from the beginning his high ideals, no less than his professional skill, made his practice successful. He gained the respect and regard of his colleagues, and the confidence and affection of his many patients. In 1913 he was elected assistant physician to the Royal Berkshire Hospital, and since 1919 he held the position of full physician. During the war, as captain in the R.A.M.C. T., he served first in Oxford, and afterwards as officer-in-charge of a large hospital in Reading.

Outside his profession Dr. Murrell interested himself in many social activities, was warden of his church, and a Past Master of his Masonic Lodge, and assisted the Conservative party in numerous elections that took place in the borough. A memorial service on June 8th was attended by many colleagues, patients and fellow-citizens.

Dr. Murrell leaves a widow, two daughters, and a son to mourn their loss.

THE League of Nations Union, in coöperation with the International Labour Organisation of the League of Nations, is organising a conference on Industrial Health, which will take place on Tuesday and Wednesday, June 19th and 20th, in the Library of the Royal Sanitary Institute, 9, Buckingham Palace-road, London. The objects of the conference will be, first, to examine how the Organisation may best assist in improving the health and welfare of industrial workers, and secondly, to secure closer coöperation between the medical profession and the Organisation and to arrive at constructive suggestions for future work. Among those who will read papers are Lord Burnham, Mr. J. H. Thomas, Colonel J. A. A. Pickard, Dr. T. M. Legge, Miss Constance Smith, and Mr. E. L. Poulton.

Correspondence.

"Audi alteram partem."

THE HOSPITAL TREATMENT OF PANEL AND OTHER PATIENTS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 2nd there appeared a letter from Mr. Raymond Shaw on the claims of non-panel practitioners, and also the abstract of a scheme for the hospital treatment of middle-class patients discussed by Sir Napier Burnett at the conference of the British Hospitals' Association at Sheffield. The two questions come into such close relationship with each other in actual practice that a few further remarks may be permitted.

That a great deal of dissatisfaction exists among the public with regard to the National Health Insurance Act (medical benefit) can hardly be contradicted. Various reasons for this have been mentioned by lay persons at different conferences, such as crowded surgeries, too many patients on doctors' lists, different treatment of panel and private patients, and so on. From the medical standpoint, while many practitioners—perhaps the majority—accept the principle of the scheme, they complain that the method generally adopted, by reason of lack of time principally, of treating symptoms by drugs instead of endeavouring to find out the cause of the symptoms by detecting the disease in an early stage, is a bad form of medical practice. Another objection is that all panel doctors, keen or indifferent, are on the same plane. There is no chance of advancement. Mr. Shaw mentions another fault of the system—the absence of freedom of choice of doctor under a contracting-out clause as was promised. For instance, a patient with tuberculosis may not be treated by whom he likes unless at his own expense, but has to be under the directions of the local tuberculosis officer, who, in many cases under the present arrangements, is more often than not a public health official—possibly a very good one—but no clinician.

The lot of the middle-class private patient is not a much happier one. To investigate an illness properly in many cases demands the services of several practitioners with experience in different branches of medicine. The result is a great expense to the patient or haphazard treatment. To meet the difficulty where hospital treatment is necessary, Sir Napier Burnett outlines a scheme whereby for a premium of £2 per annum, persons with incomes of £250 to £600 or so (Class B) should be maintained and treated in hospital when occasion arises. To administer such a scheme, it is suggested that the requisite machinery might be provided either by some private insurance company or by the existing contributory scheme organisation. Any scheme which will help to solve the problem of the treatment of the middle-class patient is to be welcomed. The recognition of the necessity for the provision of hospital accommodation for these people betokens that at last hospitals are no longer looked upon as charitable institutions in the old sense, and the further idea of payment for the members of the hospital staffs will eventually dispel the idea of the "voluntary" system which in many towns exists on paper only. There are some who will shed no tears over the passing of the "voluntary" system with its highly feudalistic and privileged system of "letters" and "turns."

In regard to the payment of the members of the staff, some may regard this as an additional asset to all the advantages already possessed—e.g., of opportunity for research, position in the profession, &c., and an extra handicap to the general practitioner outside the hospital. Such objections will be met by the necessary provision of a great many more hospital beds than at present exist, and naturally more

appointments. In my opinion, every medical man who so desires should be attached in some capacity to a hospital, whether it be of the cottage, general, or teaching variety. There will be plenty of room for all practitioners to keep in touch with hospital methods if the system at present in vogue in some towns of one man doing several jobs is abandoned. Many practitioners would welcome the extension of the National Health Insurance service on rather differently constituted lines and with the faults eliminated, and linked up with an enlarged hospital system where they can take at least some part in the treatment of their patients. To some a State medical service is a terrible thought. Their fears might be alleviated if such an eventuality could be tempered by the representation in such a service of nominees from the hospital committees as at present constituted and from the local authorities. That such a combination is not incompatible with good work was well exemplified in the war, where the united efforts of the R.A.M.C. and Red Cross achieved no mean success.

It is the fashion to throw stones at Government departments and their officials. But an example of sound medical work carried out by a State department has, in my opinion, been furnished by the Ministry of Pensions since the Armistice. Having seen a good deal of the work among pensioners, I am prepared to say, after due consideration, that in the area of which I have knowledge the work has been carried out with the greatest concord, and, thanks to exceptional administrative ability, with the highest efficiency. The result of the coöperation in the examination and treatment of men disabled in the war has been, in my opinion, one of the finest practical demonstrations of the value of team-work, both to the patients and to the medical profession. In any discussion of schemes to enlarge the scope of the Insurance Act or to alter the position of the hospitals, it will, I think, be a misfortune if the experience of the Ministry of Pensions, in dealing with large numbers of disabled men, is not invited, and carefully considered.—I am, Sir, yours faithfully,

WILLIAM STOBIE, M.D., M.R.C.P.

Oxford, June 5th, 1923.

IN MEMORY OF JOHN CHIENE.

To the Editor of THE LANCET.

SIR,—May I add a more personal tribute to the biographical notice of the late Prof. Chiene in your issue of last week? John Chiene has been away from active work for so long that he is hardly known to the present generation except as a great name, and a man about whom innumerable good stories are told. But in his day he was far more. No one in the Edinburgh school has ever wielded a stronger personal influence, or done so much to mould the characters of his students. In our time there were many fine teachers, but none who seized upon the hearts and imaginations of his boys as Chiene did. One can see reflexes of him in nearly all the senior Edinburgh men of to-day, and all his old students find themselves unconsciously adopting his mental attitude from time to time. His uprightness was a proverb, his essential cleanness of mind and clearness of thought were a daily lesson, and his kindness and humanity reached the heart of even the most heedless. With all these went the desire to see things as they really are, and to reach the essential. I am not sure that he was a great surgeon, as we understand the phrase nowadays. He did his best work during a difficult transition period, when the old surgery was done, and men were groping about rather blindly for the methods that were to make the new surgery possible. His mind, when I knew him best, was solid rather than quick, and he had neither the mental nor physical nimbleness which the new surgeon requires.

But this very defect helped him in another sphere, for what he mastered became part of himself, and he had an unequalled power of handing it on to others. It is not necessary for the student to know the very latest details in any subject; what is wanted is that

he should get a grip of principles, and should learn to observe and to draw conclusions from his observations. It was in driving principles, observation, logical reasoning into our heads that Chiene excelled. He was a master of the Socratic method, he made us observe and think for ourselves as no one else did, and he often clinched the result with some pithy or witty saying that was never forgotten. It is a pity indeed that he never collected these sayings; most Edinburgh teachers use as many as they can remember.

He was beloved as few teachers have been. We did things for him not in the hope of praise—he was chary of that—but because we loved him, and our reward was to feel that he trusted us. The time spent under him must be to thousands, as it is to me, a happy memory.

I am, Sir, yours faithfully,

Edinburgh, June 9th, 1923.

G. LOVELL GULLAND.

THE RÔLE OF THE TOOTH-BRUSH.

To the Editor of THE LANCET.

SIR,—In a letter which appeared in THE LANCET of June 2nd Sir John O'Connor delivers a startling onslaught on the tooth-brush. He attributes to its use a large number of ills, and evidently regards it as a useless and stupid fetish. Yet there is something to be said for the habit of brushing the teeth, not merely as a symbol of a certain standard of personal decency, but for its actual value in cleansing the mouth. The comparison between the anal canal and the mouth, which Sir John O'Connor draws, is obviously misleading. There is no natural method of cleaning the former region other than regular defæcation, which can be compared with the self-cleansing action of mastication. In a state of nature this latter function of the jaws and tongue should be sufficient, but since the dietetic habits of modern civilisation have seriously impaired the efficiency of the natural methods of cleansing the mouth, it seems not unreasonable, and, indeed, in accordance with physiology, to supplement Nature by methods so like her own.

In an interesting paper on the comparative anatomy of the mouth and tongue, recently read before the Odontological Section of the Royal Society of Medicine, Dr. C. F. Sonntag described the elaborate cleansing mechanism present in many animals. In the carnivora the tongue is studded with large, rough papillæ, so that the organ may be fitly regarded as a natural tooth-brush, and is used in that way with great efficiency. Not only the tongue, but other parts of the mouth are similarly furnished in many species. Dr. Sonntag showed that the digestive apparatus and the cleansing mechanism of the mouth were in inverse ratio. In the ruminants with elaborate stomachs papillæ were few; in carnivores with a simple type of stomach the tongue was rough. In man this cleansing mechanism is not so well marked, yet the tongue is capable of playing a greater part in mastication than many individuals allow, or than is recognised in the account of mastication given in text-books on physiology. The manners of good society do not permit the natural use of the tongue and lips in this way. Though this may be deplored on the grounds of hygiene, yet it is doubtful whether any enthusiast would wish to see the after-dinner habits of the larger carnivores become an established feature of modern society. This, therefore, may be taken to justify the use of the tooth-brush as an effort to imitate Nature. Being carried out in private, it does not offend the eye, though it is admittedly less efficient.

The value of the tooth-brush has undergone many vicissitudes in dental opinion. By some it has been, and still is, condemned as a useless habit which may indeed do harm. Latterly the standard of value has risen, and the majority of dentists, though alive to its abuses, allow to it a useful place in oral hygiene, if used intelligently. The tooth-brush may do harm in three ways: If used promiscuously by several individuals a tooth-brush may spread infection. The very idea is revolting to the decent mind, but it is

well to remember that among children of the poorer classes this may easily occur, and the possibility should not be overlooked. Then, again, a tooth-brush, if not cleansed after using, may easily harbour bacteria and may infect the gums instead of cleaning them. Lastly, the tooth-brush, if used with misguided zeal, can abrade both gum and tooth. Yet these risks can be guarded against. The brush should be small, the bristles should be stiff and serrated. Crosswise brushing should be avoided, for it is this which abrades the teeth and gums. The chief movement should be from the gums on to the teeth. In this way the gum receives healthy friction and the thin free edge round the necks of the teeth is not injured, neither will the enamel be eroded. The occlusal surfaces of the teeth, so often neglected, should receive attention. Following this the mouth should be rinsed, not by a passive lolling of the head but by using the muscles of the cheek and tongue to their fullest capacity. The brush should be washed in running water and either dried, or perhaps still better, placed in some antiseptic solution. Since, even with these precautions, its sterility cannot be long ensured, it should be discarded frequently. The dentifrice should be free from gritty abrasive particles. It is doubtful, however, if its chemical content is of any real significance, other than giving a pleasant freshness to the mouth and conferring on its user a somewhat fallacious feeling of security.

There cannot, of course, be any question whatever of disinfecting the mouth by dentifrice or mouth-wash. The experiments of A. L. Bloomfield have shown this conclusively.¹ Chemical and mechanical methods of cleansing the mucous membrane, so vigorous that applied as a routine method of personal hygiene they would merit your correspondent's adjectives of "inane" and "insane," completely failed to diminish appreciably the number and varieties of organisms present. The real function of tooth-brushing is mechanically to remove debris from the mouth. The purest carbohydrate, if left in contact with the teeth, will cause caries, and the use of the tooth-brush, in so far as it helps to prevent stagnation, is thus a useful and hygienic habit.

I am, Sir, yours faithfully,

Wimpole-street, W., June 6th, 1923.

A. T. PITTS.

IS DIABETES MELLITUS A PROGRESSIVE DISEASE?

To the Editor of THE LANCET.

SIR,—Dr. O. Leyton's question may be read with advantage in conjunction with the paper by Dr. G. Graham and Dr. C. F. Harris, published last week in the same number of THE LANCET. The views expressed by all of them are essentially the same. We have now had a sufficiently long experience of cases treated by alimentary rest to justify the statement that diabetes is not essentially progressive under proper dietetic conditions. Even before the advent of insulin observers interested in the subject had become familiar with cases that had become apparently stationary as a result of treatment by alimentary rest at an early stage of the disease. Unfortunately, in many cases the low caloric value necessary to keep the patient free from hyperglycæmia is inadequate to enable him to carry on any tolerable kind of existence. It is just here that insulin seems to me to be coming to the rescue. By its aid the caloric value, especially if derived from protein, fat, and 5 per cent. vegetables, can be raised to a level compatible with reasonable comfort without producing hyperglycæmia. And evidence is accumulating that if insulin be used in this way there is an increase in carbohydrate tolerance. Used otherwise, insulin appears to me to be merely an expensive palliative. I find myself, therefore, in agreement with Drs. Leyton, Graham, and Harris rather than with Prof. Maclean.

I am, Sir, yours faithfully,

W. LANGDON BROWN.

Cavendish-square, W., June 9th, 1923.

THE STEINACH OPERATION.

To the Editor of THE LANCET.

SIR,—Through the courtesy of a medical friend I was given the opportunity of witnessing Dr. Burchardi perform upon him the Steinach operation for enlarged prostate. The operation, although simple and quickly performed, requires skill and delicacy of manipulation to avoid wounding the blood-vessels and nerves of the cord, and thereby producing atrophy or gangrene of the testicle. If the prostate is much enlarged, Dr. Burchardi ties and severs both vasa. The resulting sterility does not destroy sexual desire or capacity for intercourse, but often has a rejuvenating effect. My old friend, the late Dr. Reginald Harrison, was, I believe, the first surgeon to advocate and perform section of the vasa for enlarged prostate, but his operation proved a failure owing, I imagine, to the fact that the blood-vessels and nerves of the cord were also severed. Nothing was known in those days concerning the internal secretion of the testicle. Probably Dr. Harrison's failure is the chief cause of the scepticism existing among the medical men of this country with regard both to the effect on the prostate of section of the vas and the more general effect of rejuvenation.

I am, Sir, yours faithfully,

Streatham, June 12th, 1923.

R. MANSELL-JONES.

L'AFFAIRE SPAHLINGER.

To the Editor of THE LANCET.

SIR,—Last year, having been commissioned to report on the Spahlinger treatment, I visited Geneva, and, by the courtesy of Mr. Spahlinger, was allowed to examine his cases under treatment and cases discharged cured. I was given access to the clinical and photographic records, and shown in detail the laboratory with its many original mechanical devices for the production of serum and vaccine on a large scale. On returning to London I examined a further series of cases which had been treated in 1913 and 1914.

I believe that Mr. Spahlinger has discovered a means of dealing successfully with all types of tuberculous infection in any stage. The method of preliminary disintoxication with serum enables us to be hopeful even in the most advanced cases, and, by means of subsequent vaccination, relapse is effectively guarded against. By using both human and bovine bacillary strains the infection, whether pulmonary or non-pulmonary, may be equally successfully treated. Of even greater significance are the possibilities opened by the use of the vaccine prophylactically. It has been shown by Mr. Spahlinger that vaccination produces a powerful immunity in cattle as well as in human beings. Are we not here shown a clear road to the ultimate eradication of this scourge?

The majority of medical men appear to be still either ignorant or uninterested in this treatment. Among the interested who are not favourably impressed are those who condemn it as a "secret remedy," or who say that, without knowing the minute details and technique of preparation, they are unable to express an opinion on its scientific value from a bacteriological point of view. Mr. Spahlinger makes no secret of his theories, bacteriological principles, or laboratory methods. Surely these in conjunction with the clinical evidence are sufficient: the precise formula would not help most of us in judging its efficacy. We have already had many theoretically sound, but clinically useless, methods of treatment for this disease. The other class of critic who impatiently demands further proof is unmindful of the number and high reputations of the men who, having used only partial sera, have shown such extraordinary results.

I am, Sir, yours faithfully,

HUGH A. WYLLIE, M.B., B.S. Adelaide.

London, June 9th, 1923.

DEFECTIVE LIPOLYSIS IN DIABETES
AND CANCER.*To the Editor of THE LANCET.*

SIR.—The discoverers of insulin have shown that this substance not only has an effect on the blood-sugar but also on the utilisation of fat. This utilisation of fat is defective in diabetes, and insulin markedly improves it and rapidly removes any lipæmia if present. This latter action is specially interesting to me because for many years various aspects of the fat-splitting action of the pancreas have been the object of research by myself and other workers in this laboratory.¹ The main outcome of this work has been to show that lipase in extracts of the pancreas consists of two components, one of which, following current nomenclature, is spoken of as the *coenzyme*, and the other *inactive lipase*. The coenzyme when produced in the pancreas, or after injection, appears to be distributed by the blood to the tissues, activating the lipases there. We concluded further that this activating property is due to organic and inorganic phosphates. Whether the islets of Langerhans are responsible for the formation of the coenzyme, or not, appears uncertain. The same uncertainty is seen in De Witt's experimental work.² My object in writing is to call the attention of workers to this aspect of the question, and more especially in relation to cancer. My experiments showed that tissue lipolysis is defective in cancer. I am convinced that increased tissue lipolysis is a factor in the defensive processes of the body, and this is particularly the case in cancer. Anything which increases this action in that disease should not be lost sight of.

I am, Sir, yours faithfully,

J. A. SHAW-MACKENZIE, M.D.Lond.

Physiological Laboratory, King's College, London,
June 8th, 1923.

DELAY IN GIVING DIPHTHERIA ANTITOXIN.

To the Editor of THE LANCET.

SIR.—Dr. E. E. Caiger's³ letter intimately concerns general practitioners as a body, and demands consideration by those who possess intimate knowledge of the conditions under which general practice is carried on, especially in an industrial area. Antitoxin is now supplied gratuitously by the medical officer of health, but only for individual cases—that is to say, it is not possible to obtain a supply to have ready to hand for immediate use, but one has to apply for a supply for the particular case for which it is wanted; this means delay in obtaining the serum. In my opinion, if a case is sufficiently suspicious to call for the use of antitoxin, it is far better to send it straight off to hospital to be under the observation which cannot be secured at home. The authorities are very smart in sending down the ambulance, and one can rely on getting the case into hospital within two hours of examining it.

I once discussed this view with the late Dr. H. E. Cuff, and he entirely agreed with me. If you depend on the early administration of antitoxin by the family doctor, you have several difficulties to contend with. The delay in obtaining it; the objection raised by some parents to its use (in hospital it can be given without asking for consent); the danger of losing touch with the patient, owing to not having a supply of antitoxin to hand, until the case has become advanced. Moreover, the risk of anaphylaxis in non-diphtheritic cases is not negligible, and after a dose of antitoxin the patient should be under observation.

¹ Rosenheim, O., and Shaw-Mackenzie, J. A., 1910 (I. and II.); Rosenheim, O. (III.), *Proc. Physiol. Soc., Journal Physiology* xl., pp. 8, 12, and 14. Shaw-Mackenzie, J. A., 1911 (IV.), *ibid.*, xlii., p. 11; 1913, *Internat. Congress Med. (Therap. Sect.)*; 1915, *Journal Physiology*, xlix., p. 216; 1919, *THE LANCET*, ii., p. 825; 1921, *Jour. Trop. Med. and Hyg.*, i., p. 161; 1922, *Med. Press and Circ.*, i., p. 287; 1922, *THE LANCET*, ii., p. 769.

² De Witt, L. M.: 1906, *Jour. Exp. Med.*, viii., p. 193.

³ *THE LANCET*, June 9th, p. 1189.

After 25 years' experience of practice in an industrial area, I am convinced that early removal is the soundest procedure. I always explain to the parents that the case is a doubtful one (when the signs and symptoms do not warrant a precise diagnosis); that, if it proves to be diphtheria, early removal will have given the child the best chance of recovery; that, if it does not prove to be diphtheria, the child will run no risk by being removed to hospital and will return home after a short detention. The majority of advanced cases that are sent to hospital are in an advanced stage when the doctor first sees them. That a few doctors do delay until diagnosis is assured is probable, and for this the M.A.B. itself is largely to blame, for they used to send a notice to practitioners, when a case proved not to be one of infectious disease, stating that it was not diphtheria or other notifiable disease. In my borough one of the borough councillors on the health committee used to keep a black list of doctors who had numerous cases notified to them in this way. It is hardly to be wondered at if this attitude made some practitioners unduly careful not to send a case in until they were sure of the diagnosis, and the idea thus propagated has not entirely died out.

I do not know of any doctor who entertains the idea set out in Dr. Caiger's last paragraph.

I am, Sir, yours faithfully,

HENRY J. CARDALE.

Cubitt Town, E., June 10th, 1923.

A STANDARD FOR LYSOL.

To the Editor of THE LANCET.

SIR.—We should like to bring to your notice the anomalous position regarding lysol which now obtains. This preparation was a 50 per cent. solution of cresylic acid in soap, and the product as originally sold under the proprietary name "Lysol" always contained a minimum of 50 per cent. free cresylic acid. Now, however, owing to the name having been thrown open generally, all kinds of preparations are placed upon the market which contain a far less proportion of cresylic acid. In fact, we know that a preparation is being sold to-day by unregistered druggists which actually contains less than 3 per cent. of cresylic acid.

The position is that there being no official standard for lysol, anyone to-day can make a preparation containing practically no cresylic acid whatsoever and can call it "Lysol," and thus the medical man as well as the public might easily be misled into thinking that they are buying a preparation of the original strength. The danger lies in the fact that the bactericidal power of the preparation resides almost solely in the cresylic acid content. Lysol is probably the most used antiseptic in midwifery, and if a preparation is used containing only 3 per cent. of cresols the patient may run a grave risk of septic conditions, whilst the practitioner is thinking that ample protection is provided by the antiseptic.

In the generality of products which have a common name the public are protected either by such preparations being standardised and made official in the Pharmacopœia, or by standards especially maintained under the Food and Drugs Acts. We have already brought the matter before the General Medical Council, who have undertaken to refer it to the Pharmacopœia Committee when a revision is next called for, but in the meantime the public are left unprotected. We should be glad to leave it to any pressure could be brought to bear in order that a standard might now be laid down for this important product.

I am, Sir, yours faithfully,

S. H. MARSHALL,
Director, Lysol, Ltd.

Raynes Park, London, S.W., May 29th, 1923.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH. *City of London.*

Dr. W. J. Howarth's report for 1922 gives the mid-year population of the City as 13,363. The birth-rate was 11.1, the death-rate 14.1. The death-rate from tubercle was 1.5, from cancer 1.6, and from respiratory diseases with influenza 3.0. There were no maternal deaths from childbirth and no deaths among illegitimate infants, while the mortality-rate for legitimate infants was 66. Two improvement schemes have been sanctioned: the Queen's Court, Minories area, involving the provision of dwellings on the site for 72 persons, and the Hutchinson-street area, providing for the rehousing of 250 persons on the site and 635 elsewhere. The occurrence of a case of anthrax in a neighbouring borough was associated with Chinese bristles and Russian horse-hair, and the bristles were apparently contaminated by the horse-hair. The Court of Common Council have urged the Ministry to give effect to the recommendations of the Smoke Abatement Committee, particularly those which empower the Ministry to act in default and to fix standards and those which lay on manufacturers the obligation to provide the best practicable means for smoke prevention and enable larger fines to be imposed than at present.

Mr. T. D. Young, the veterinary surgeon at the meat markets, reports on Australian frozen beef. Considerable loss is caused to the trade, both from the imperfection of the freezing methods and from infection with *Onchocerca gibsoni*, and Mr. Young recommends further research in Australia with a view to finding remedies. The meat passed through the central market amounted to 463,074 tons, which constitutes a "record." Supplies from South America increased by 12 per cent. and from Holland by 58 per cent. British feeders supplied 30 per cent. of the pork. Dr. Howarth comments on the large amount of diseased British meat, showing that the recommendations of the Departmental Committee on Meat Inspection are not receiving due attention. Much money is being saved by more scientific methods of dealing with pig carcasses affected by tuberculosis. Argentine lamb continues to improve in quality and to approach nearer to the New Zealand standard, but there is room for improvement in both New Zealand and Australian beef.

Dr. Howarth deals with the question of boric acid in cake, due to the use of boracised egg-yolk. The Bakery and Allied Traders' Association have undertaken to help to prevent boracised egg-yolk being used for this purpose. He hopes to present a report on standards for preservatives in the very near future. Rat repression continues to receive careful consideration and is rendered more difficult by the fact that accommodation in increasing amount is being provided for the consumption of food on the premises by employees.

Norwich.

Dr. H. Cooper Pattin states that the general features affecting the health of the community in 1922 which called for comment were: (a) influenza in epidemic form at the beginning, (b) scarlet fever at the end of the year; as there had been relative freedom from scarlet fever, in anything approaching an epidemic, for years, a considerable population at susceptible ages had grown up who fell ready victims to the epidemic; (c) throughout the year relative prevalence of unemployment among sections of the population, which reacted badly upon the general standard of nutrition and healthiness. The notifiable diseases were as follows:—

Cases notified.		Deaths.	Cases notified.		Deaths.
Diphtheria ..	177	12	Malaria ..	3	—
Scarlet fever ..	682	2	Erysipelas ..	54	3
Enteric fever ..	8	2	Encephalitis ..	5	3
Puerperal fever ..	6	4	lethargica ..	5	3
Pneumonia ..	95	46			

There were 191 notifications of tuberculous disease during the year—150 of the lungs, and 41 of other forms. There was a fractional majority of males affected; 37.7 per cent. were married, 58.6 single, 3.7 widows. Information obtained from 149 of the cases revealed evidence of family taint in 29.5 per cent. At the time of the first visit 46.3 per cent. occupied a separate bedroom, 10.7 per cent. a separate bed in a double-bedded room, and 43.0 per cent. shared a bed with another (presumptively non-tuberculous) person. The deaths from phthisis numbered 135, and from other tuberculous diseases 32. (In 1921 the corresponding figures were 147 and 26.) As usual, boot-workers contributed, next to housewives, most largely to the numbers, there being 25 boot-workers notified in 1922—three less than in 1921. 129 pulmonary cases were admitted to hospital, colony, or sanatorium during the year, and 30 non-pulmonary. The conjoint Stanninghall Colony and the Pavilion (for women) at the Isolation Hospital rendered good service. Dr. Pattin does not think that the provision of institutional treatment for cases past hope of recovery is likely to serve any useful purpose unless and until statutory power of compulsory segregation is conferred. As to maternity and child welfare work, at or from the maternity institution 323 confinements were attended (25 more than in 1921), 38 in the wards, and 285 outside; 99 of the mothers attended the ante-natal clinics. The infant welfare clinics did good work during the year; 951 new babies were brought and the total number of attendances was 8769. Inspection of 6900 children in the elementary schools revealed defects sufficiently serious to need medical treatment in 12.4 per cent. Among 580 scholars in the secondary schools 49, or 8.4 per cent., required medical treatment. The school dental officer finds defects in the teeth of 73 per cent. of those whom he inspects. The scarcity of houses persists. Only 183 houses of all types were erected during the year, 161 of these as part of the municipal housing scheme. This scarcity compels the health authorities to tolerate the continued occupation of numbers of undesirable habitations, prevents compulsory closure, and leads to overcrowding. A feature of much house property in the city is its worn-up character, which makes reparation unprofitable.

Cardiff Port Sanitary Authority.

Dr. Ralph M. F. Picken reports that some anxiety arose in October last when sailors from a ship arriving at Cardiff, who had disembarked before the vessel's arrival at Cardiff, introduced small-pox at Barry, at a time when it was prevalent in other parts of the country. None of the 205 rats examined showed evidence of plague, but the fact that Dr. J. J. Simpson found the flea which is known to convey plague on rats caught both on vessels and on shore shows that the conditions precedent to the transmission of plague exist in the port area. Dr. Simpson gives some interesting particulars. The species known as brown rats and black rats are often confused. All the rats sent to him were black rats. Colour is no guide. Some "brown" rats are black and most "black" rats are brown. Illustrations of the two species are given. The black rat is more elegant, has a sharp muzzle, weighs about 8 oz., has large translucent ears and a slender tail, often longer than its head and body. The brown rat is of clumsier build, has a blunt muzzle, weighs 14 oz. or more, has small hairy opaque ears and a stout tail, never as long as the head and body combined. Of the three species of flea obtained, the plague flea, *Xenopsylla cheopis*, was found on three rats from warehouses and five from ships. One of the five ships had a case of plague on board in May, 1922, from Rangoon to Thursday Island. On arrival at Sydney the ship was fumigated and 57 rats were found, some of which were plague-infected. At Barcelona the ship was again fumigated. Treatment for sailors suffering from venereal disease is provided at the Royal Hamadryad Seamen's Hospital. The attendances reached a maximum of 17,040 in 1919 and have exceeded 12,000 in each of the three subsequent years.

SCHOOL MEDICAL SERVICE.

Warrington.

OUT of 4519 children examined in the routine group, 839 had defects requiring treatment, and of these 536, or 63·8 per cent., were treated. Every school in the town is visited by a school nurse twice a week and minor ailments are dealt with on the spot. In this connexion 47,513 dressings were done in the schools and Dr. G. W. N. Joseph claims that 75,000 school attendances were saved in this way. Out of 1309 entrants examined 166 had attended a welfare centre. The increase in the number of verminous heads is attributed to the higher standard of cleanliness adopted by the nurses. Ringworm cases treated by means of X rays numbered 54 at a cost of £84 10s. After the treatment these children attend the clinic for three days a week, when the head is washed with ether soap and white precipitate ointment is applied until the child is fit to attend school, after which he wears a washable cap in school and is treated by the nurse on her two weekly visits to the school. The school dentist inspected 10,782 children, 74·5 per cent. of whom had dental defects. He examines an average of 70 children per school session and treats about 12 a session at the clinic. There are now three schools in Warrington with school baths. Few objections are raised by parents to the children having the weekly bath, and in nearly all instances such objections are based not on the fear of any detriment to the child, but on the fact that the child's underclothing may be defective or uncleanly. An inquiry was made into the relationship between home conditions and the mental and physical capacity of school-children. The total number of cases investigated was 366. Dr. Joseph has come to the conclusion that of the three factors—overcrowding, bad hygienic conditions, lack of parental care—overcrowding in itself is the least deleterious to the child's mental and physical condition, and lack of parental care, even unaccompanied by bad hygienic conditions, is the most pernicious.

Cambridge.

There are 23 elementary schools in Cambridge with an average attendance of nearly 7000. Just over 2000 children were medically examined at routine inspection, and of 181 referred cases 163 received treatment. There were no cases of skin disease or of uncleanness recorded at this inspection, and Dr. A. J. Laird considers that the constant and firm pressure exercised upon persistent offenders (police court proceedings were taken in 89 cases) has made them realise that it is wiser to keep their children clean than to pay fines in the police court. A substantial part of the nurses' time is taken up with this work, the number of nurses' inspections for this purpose being 16,884. The head teachers, too, are very hard on offenders, in some schools making them occupy seats apart from the other children. This is said to have a more deterrent effect than any measure yet tried. The annual report of Cambridge for 1907 recorded nits or pediculi in the heads of 84 per cent. of the girls. The percentage has been reduced to 16·1.

Durham.

Over 41,000 children were medically inspected, and of 28,298 routine cases 8566 were referred for treatment, 8169 being kept under observation. Of these, 770 were found to have skin disease, 4528 defective vision, 5138 disease of the nose and throat, 280 speech defect, 462 ear trouble, and 707 defective hearing. Towards the end of the year zinc ionization for otorrhoea was introduced. During the year 7403 children received treatment out of 15,590 referred cases. About one-half of the dental cases were left untreated owing mainly to the shortage of clinics and dental staff. One of the doctors remarks a general improvement in cleanliness among children of employed and unemployed alike. This she attributes to two factors besides the efforts of doctors, nurses, and teachers—the aesthetic effect of feeding centres and the fashion of bobbed hair. The amount of feeding is considerably less than for 1921, owing to the limitation of the grant given by the

Board of Education for this purpose. The number of malnutrition cases found at routine inspection in the elementary schools was 1636, and in the secondary schools 222 out of 4471 children examined. The medical officer of the Birtley school clinic remarks that among those attending for examination and advice the class in which no physical cause for the impairment of general health is discoverable has been more in evidence during the late autumn, a fact which, he says, is undoubtedly due to bad family circumstances. Often a clue is supplied by some extraneous detail, such as poor clothing or lack of boots. He also notes enormous increase in the amount of septic skin conditions, which show a marked tendency to recur after apparent cure; he has little doubt that this increased susceptibility to septic infection is another indication of lowered vitality, coupled, perhaps, with injudicious household economy in the matter of soap and water. Investigations by two school doctors into the causes of laziness and of backwardness in children are interesting. Dr. G. C. M. M'Gonigle asserts that probably 90 per cent. of laziness can be traced back to physical causes, that laziness is a protective state and merely a symptom of a fundamental cause such as deafness, adenoid growths, anæmia from toxic poisoning, lack of sleep, improper feeding, or thyroid deficiency. Dr. H. G. Donald lays particular emphasis on laxity of home discipline and domestic mismanagement as factors in producing the dull and backward child. The undisciplined child of 5 is backward at the start of school life, and in most cases the subnormality is of ante-school origin. As an actual cause of dullness intra-school influences probably do not count at all. The remedy suggested is the supervision of children up to school age. It is possible that Durham will consider it worth while to establish a nursery school for this important research work. Dr. Eustace Hill attributes the greater part of this well-written report to the deputy school medical officer, Dr. A. T. Paterson. The suggestion at the end for health talks to children should be useful to doctors and teachers alike.

Medical News.

UNIVERSITY OF OXFORD.—At recent examinations the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH.

Part I.—Walter H. Butcher, Weldon Champneys, and Manuel J. Saldanha.

Part II.—Weldon Champneys and Mary Phoebe Wilson.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following have been admitted (after examination) as Fellows of Faculty:—

Robert A. Anderson, M.B., Ch.B.; George Dalziel, M.C., M.B., Ch.B.; Leander L. Fyfe, M.B., Ch.B.; George W. Hill, M.D.; James H. Martin, M.D.; and Sundar Das Sondhi, M.B., B.S.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—The chairman, Lord Chelmsford, and members of the University College Committee, the Provost and members of the academic staff, will hold a reception at the College on July 7th. The new anatomy building and the extensions of the physiology and engineering departments will be open to inspection. Old students of the College who have not recently communicated their addresses, are invited to send them, stating year of entry and faculty, to the Secretary.

UNIVERSITY OF MANCHESTER.—At its meeting on June 11th Convocation elected the Earl of Crawford and Balcarres to the office of Chancellor of the University vacated by the resignation of Viscount Morley of Blackburn.

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS.—At the last meeting of the session, to be held on June 20th, at 8 P.M., in the Essex Hall, Strand, Mr. John Lort-Williams, K.C., M.P., will lecture on Birth Control as it interests Me.

THE Minister of Health will make an informal inspection at 2.15 P.M. to-day (Saturday) of the new pathological laboratories at Hollymoor near Birmingham set up by the Joint Board of Research for Mental Diseases and the Birmingham Asylums Committee.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The George Alexander Gibson memorial lecture will be delivered in the hall of the College, 9 Queen-street, Edinburgh, on June 27th and 28th at 5 P.M., by Dr. W. T. Ritchie. The subject will be the Response of the Heart in Health and Disease.

NORTHWICH HOSPITAL.—Sir John Brunner and his brother, Mr. Roscoe Brunner, have jointly endowed a Brunner bed in Victoria Infirmary, Northwich, in connexion with the celebration of Messrs. Mond, Brunner and Co.'s jubilee.

SOCIETY OF BIOMETRICIANS AND MATHEMATICAL STATISTICIANS.—Dr. T. H. C. Stevenson will give a paper on the Social Distribution of Causes of Death in England and Wales on June 25th at 8 P.M., in the Theatre of the Galton Laboratory, University College, Gower-street. Visitors will be welcomed.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A special course in Neurology will be given at the West End Hospital for Nervous Diseases from June 25th to July 20th. Demonstrations in the outpatient department will take place each day and lecture demonstrations specially dealing with the diagnosis and treatment of nervous disease will be given by members of the staff three times a week. The Fellowship programme for July will include a two weeks' refresher course at the Royal Northern Hospital in conjunction with the Central London Ophthalmic Hospital and the Royal Chest Hospital, from July 2nd to 14th and concurrently with this a fortnight's intensive course in cardiology will be given at the National Hospital for Diseases of the Heart. There will also be special courses on dermatology at the Hospital for Diseases of the Skin, Blackfriars, from July 16th to the 28th and on Diseases of Children at the Royal Waterloo Hospital from July 16th to August 4th. Further particulars can be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole-street, London, W. 1.

THE LATE DR. F. E. RAINSFORD.—Frederick Edward Rainsford, M.D. Dub., medical superintendent, Stewart Institution, who died at Palmerstown House, Palmerstown, on June 6th, spent the first part of his professional life at Fishponds Asylum, Bristol, where he was a senior member of the medical staff, and from where he was appointed in 1898 as medical superintendent to the Stewart Institution for Imbeciles and to the Hospital for Mental Diseases, Palmerston. He received his early education at Old Rathmines School. An all-round athlete, he played for the Lansdowne XV. and the Trinity cricket team in his earlier years, and later organised a famous cricket team at the Institution. He was deeply interested in his profession, and held the post of an examiner in medicine in the University of Dublin; during his tenure of office at Palmerstown he greatly enlarged and brought up to date the two large institutions under his care. He was of an energetic and cheerful disposition, being very popular with his patients and employees, and held in high esteem by his colleagues. The strain of the war years, when most of his staff was called up for service, coupled with the many agricultural difficulties he had to cope with in his administrative work, told on his health. Although warned by specialists to "go slow" he carried on till a break-down last year.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—Lord Howard de Walden, who presided at the annual meeting of governors on May 30th, referred to the serious financial position of the hospital. There was a debt of £20,000 and the hospital had had to deposit all its securities against the overdraft at the bank. As this was not sufficient the committee had been compelled to take steps to raise money on the security of the freehold of the hospital in the hope that their friends and the public generally would help them to pay off this mortgage and thus prevent any curtailment of the good work of the hospital. The numbers of patients seeking admission were greater than ever, and it would be disastrous if it became necessary to reduce the accommodation for patients and the facilities provided for the training of students, maternity nurses, and midwives, who came to the hospital from all parts of the country and our dominions. Last year 155 students and qualified practitioners attended a course of practical midwifery at the hospital, and practically every vacancy was filled for the next 18 months; while 172 women had been trained as maternity nurses and midwives. During the year 150 candidates took the Central Midwives Board examination and only six failed to pass, the percentage being 4, as compared with 23 of failures throughout Great Britain. The accommodation of the hospital was quite inadequate for the great demands made upon it, and it was impossible to carry out the proposed extensions and alterations until the debt was paid off. He made an earnest appeal for additional support.

ORDER OF ST. JOHN OF JERUSALEM IN ENGLAND.—The King has sanctioned the following promotions and appointments: Major Arthur Hammersley Johnston, M.R.C.S., Dr. George Herbert Rose Holden, and Dr. Harry George Walters, as Knights of Grace; and Captain James Anderson, M.D., and Major Cecil Henry Elmes, V.D., M.B., Esquires.

ROYAL MEDICAL BENEVOLENT FUND.—At the meeting of the committee held on June 5th 36 cases were considered and £510 5s. voted to 32 applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 56, of M.D. St. And. who practised in Surrey and died in 1919. Through lameness and also not being physically strong applicant finds it difficult to obtain a permanent post. She is at present in a post, and has received £20 in the last six months. She also receives £26 from the R.U.K.B.A., and £28 from her brother towards rent, which, with partial board, amounts to £72 per annum. Voted £12 in 12 instalments.

Daughters, aged 54 and 57, of M.R.C.S. Eng. who practised in Kent and died in 1920. The father's estate was in the hands of a solicitor, who embezzled three parts of the money. The sole income of these ladies amounts to £40 per annum each, and the amount left of the estate, which is now cleared up, is £147 to each. Rent, 12s. per week each. Voted £12 in 12 instalments each.

Wife, age 60, of L.R.C.P. & S. who practised in Hull. Applicant's husband has been in an asylum for 24 years, and has received help from the Medical Sickness Assurance Society, but having reached the age-limit there is no further assistance from this source. Applicant asks for help to pay the life assurance premiums, which amount to £10 per annum. Voted £10.

An anonymous donation of £5 from a Bath subscriber was received for the benefit of a case mentioned in our last report. The amount has been duly forwarded and received with grateful thanks.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

RESEARCH DEFENCE SOCIETY.—The annual general meeting will be held at the house of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W. 1, on June 20th, at 3.30. The chair will be taken by Lord Lamington. A short lantern lecture will be given by Dr. C. W. Saleeby on Sunlight and Disease. The report of the committee records a great improvement in membership. During the past few months more than 450 new members have been gained. A number of lectures and debates have been held, and their results have been very satisfactory. These lectures and debates have been particularly useful in dealing with the mis-statements of the anti-vivisection societies. The work of teaching is to be extended. The collection of slides available for lantern lectures on such subjects as the work of Pasteur and Lister should be noted. The Dublin branch of the Society has decided that, in view of the separate government of Southern Ireland, there ought not to be any official connexion with the parent society. The Dublin branch is therefore dissolved, but the hon. secretary, Mr. J. W. Tullo, is forming a new association, so that the defence of research will not be interrupted. Captain Walter Elliott having had to resign his position as Hon. Parliamentary Secretary of the Society, Sir Sydney Russell-Wells has succeeded him. The hon. treasurer's report shows for 1922 an income of £806 and an expenditure of £948, indicating an excess of expenditure over income of £142. As the result of an appeal by Lord Knutsford, chairman of the committee, there has been a considerable increase in the subscriptions and donations, but these will not favourably affect the balance-sheet till the close of the present year.

SHEFFIELD HOSPITAL SERVICE.—At a recent meeting of the Grand Lodge of the Sheffield Equalised Independent Druids an address by Mr. S. R. Lamb (secretary of the Sheffield Joint Hospitals Council) was read. The whole tendency of modern hospital accommodation, Mr. Lamb wrote, was to unify the various departments. All hospital beds in a city should be under one roof, in order to secure for each individual patient the advice and help of all or any specialists in their own particular sections of modern medicine. Such a hospital should be equipped with the most modern apparatus, and a laboratory having its own pathological staff. Sunlight and clean air were two of the greatest factors in curative medicine, and arrangements should be made to provide a convalescent department to which patients could be sent. If for a year men would go without tobacco and cigarettes for one day in each week, they could provide the country with enough money to enable medical scientists to investigate the cause of the modern curses ravaging this country to-day. The claim of the manual workers was gradually receiving the attention it deserved, but there was a big section of the "middle classes" relatively as dependent upon the voluntary hospitals whose claims had not been so generously recognised. Dealing with the question

of a municipalised, or nationalised, system, Mr. Lamb believed there was a spirit and soul in the voluntary system which might be absent once hospitals were governed from the town hall or from Whitehall. Contributors and their families, representing 250,000 of the local population, were actively assisting in reconstructing Sheffield hospitals by offering money and service. Sheffield was almost the lowest in the list of industrial centres in regard to the number of voluntary hospital beds per 1000 of the population. There was still a debt of nearly £80,000, and until this was wiped out their efforts would be crippled. The aim was to have a large unified general hospital away out on the hill-sides. The Royal Infirmary site might some time be used as a public park, the Royal Hospital as a casualty hospital, and Jessop Hospital as a maternity hospital.

GUY'S HOSPITAL.—H.R.H. the Prince of Wales, as President of the hospital, will open the new anatomy, biology, and vaccine departments of the Medical School at 3 P.M. on Monday, July 2nd.

MEDICO-LEGAL SOCIETY.—A meeting of this society will be held at 11, Chandos-street, London, W., on June 19th, at 8.30 P.M., when Dr. A. S. Woodward will read a paper on *Some Attempts to Defraud Life Assurance Companies*, to be followed by a discussion.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—The foundation-stone of the Nurses' Home at the country branch of this hospital, Brockley Hill, Stanmore, will be laid by H.R.H. Prince Henry on Saturday afternoon, June 23rd. The formal opening of the new Hut will take place at the same time.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. and Bt. Lt.-Col. C. G. Browne, from the half pay list, is restd. to the establt.

Maj. M. C. Beatty to be Lt.-Col., vice Lt.-Col. H. Herrick promoted.

Temp. Capt. A. G. McKenna relinquishes his commn. and retains the rank of Capt.

Col. R. J. Blackham, half pay list, late R.A.M.C., retires on ret. pay.

J. M. Jamie to be temp. Lt. whilst empld. as a Dental Surgeon.

ARMY RESERVE OF OFFICERS.

Col. T. B. Beach, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. F. F. Burghard, having attained the age limit, is retired and is granted the rank of Col.

Capt. H. N. Crowe relinquishes his commn. and retains the rank of Capt.

Supernumerary for service with O.T.C.: Capt. G. A. Williamson to be Local Major whilst comdg. the Aberdeen University Contingent, O.T.C.

General Hospitals: Lt.-Col. G. R. Turner, having attained the age limit, is retired, and retains the rank of Lt.-Col.

The undermentioned officers relinquish their commns. and retain their rank except where otherwise stated: Lt.-Col. F. W. Ellis; Maj. W. S. V. Stock and A. Young; Capt. E. C. Bradford, C. F. Coombs (granted the rank of Maj.), C. C. Cuthbert, A. G. T. Fisher, A. A. R. Green, A. R. Short, and W. Whitelaw.

Sanitary Companies: Capt. A. F. MacBean relinquishes his commn. and retains the rank of Capt.

Capt. T. L. Fraser to be Div. Adjt., 51st (Highland) Div., T.A., vice Capt. C. Popham, transferred to 49th (West Riding) Div.

TERRITORIAL ARMY RESERVE.

Maj. (Bt. Lt.-Col.) C. Rundle, from 1st Western Gen. Hospl., T.F. Res., to be Lt.-Col.

Maj. A. M. Gossage, having attained the age limit, is retired, and retains the rank of Maj.

THE WAZIRISTAN OPERATIONS.

Among the names brought to notice for distinguished service during the operations in Waziristan, 1920-21, by His Excellency General Lord Rawlinson of Trent, are the following: Col. W. E. Hudleston (late R.A.M.C.) (Staff Command); Maj. H. Harding (A./Lt.-Col.); Capt. A. G. Biggam (A./Lt.-Col.); W. M. Cameron (T./Maj.); C. M. Ingoldby (A./Lt.-Col.); J. M. MacKenzie (A./Maj.); C. Popham (A./Maj.); M. P. Power (A./Maj.); T. H. Sarsfield, B. C. O. Sheridan, R. I. Sullivan, all of the R.A.M.C. Lt.-Col. C. Hudson (A./Col.), I.M.S.; Matron Miss E. O'Sullivan, R.R.C.; Capt. J. B. Vaidya (A./Maj.), I.M.S.; and Temp. Capt. G. D. D. Wijesekere, I.M.S.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JUNE 12TH.

Mental Treatment Bill.

THE Mental Treatment Bill was considered on report and was ordered for third reading.

HOUSE OF COMMONS.

TUESDAY, JUNE 5TH.

Carbon Monoxide in Gas.

SIR WILFRID SUGDEN asked the President of the Board of Trade whether his attention had been drawn to the description in the press of a method of treating gas by a Mr. Tully whereby, so it was alleged, the percentage of carbon monoxide was very greatly reduced; and whether he had any information as to the practicability of producing such a gas upon a commercial scale.—SIR P. LLOYD-GREAME replied: The latest analysis which I have seen of gas produced by Tully plant at present in industrial use, which was published on May 16th in the *Gas Journal*, gives the carbon monoxide content as 37 per cent., but I observe that in a prospectus just issued, which my hon. friends have no doubt seen, it is stated that by means of a new converter the carbon monoxide content can be reduced to a negligible quantity. I am not in a position to express an authoritative opinion as to the practicability of producing town gas on a commercial scale by the new process. The matter is, however, being carefully watched by the Government departments concerned.

WEDNESDAY, JUNE 6TH.

Rockefeller School of Hygiene.

MR. RHYS DAVIES asked the Minister of Health to state the present position regarding the Rockefeller School of Hygiene; what was the estimated annual cost of its upkeep and from what source its income would be obtained; what were the names of the council of the governing body; and who was the director of the institute by whom these persons were chosen or, if they had not yet been appointed, by whom they would be chosen.—LORD E. PERCY replied: A formal agreement has been entered into between the Rockefeller Foundation, the Minister of Health, and London University, and the site for the school has been selected. The Government have accepted the liability for the maintenance expenses up to an amount not exceeding £25,000 a year, which, together with fees and any transferred endowment, is expected to be sufficient. The permanent governing body cannot be appointed pending the completion of the negotiations with the existing schools and other bodies concerned; and my right hon. friend has accordingly appointed a transitional executive committee including, besides himself and Lieut.-Colonel Fremantle, Lord Burnham, Sir Arthur Clarke, Sir Walter Fletcher, and Sir Harry Goschen, Sir George Newman, Sir Cooper Perry, and Sir Arthur Robinson. This committee will carry on the preliminary work until the permanent governing body can be established, and one of their first tasks will be the selection of the director.

DR. CHAPPLE asked the Minister of Health why, in view of the fact that the interests of women in national health would be largely involved, no women had been included among the appointments he had made to the transitional executive committee of the proposed school of hygiene; and whether he would add to its members at least two women.—LORD E. PERCY replied: My right hon. friend is unable to agree that the interests of women will suffer in any way from the fact that no women have been appointed to the transitional executive committee, and the duties entrusted to that committee do not appear to him to necessitate the appointment of women as such without regard to their other qualifications.

Maternity and Child Welfare in Hornsey.

Captain Viscount EDNAM asked the Minister of Health whether his attention had been drawn to the reply sent by the Hornsey borough council to the Ministry's letter, dated April 12th, in which it was stated that if the council kept within the amount which the Ministry recognised for grant in respect of child and maternity welfare it would be impossible to carry on the work efficiently; and whether, in view of their reply, he would reconsider his decision to reduce the estimate furnished by the council by £100.—LORD E. PERCY replied: My right hon. friend is aware of the report of the medical officer of health and of the letter from the Hornsey borough council referred to. The reduction of £100 was made in the absence of any explanation of the purposes for which the sum was required. The council have now applied for approval of an extension of their

ante-natal work. After consideration of the report of one of the medical officers of the Ministry, who has investigated the proposal, the Minister of Health is prepared to agree to an addition to the expenditure of the council for the purpose of ante-natal centres.

Panel Practitioners' Records.

Dr. WATTS asked the Minister of Health of what use the records kept by panel doctors are, either from a scientific or other point of view, and what was the cost to the insurance funds; and was he aware that the fact that these records had to be kept stopped many insured persons, especially when suffering from certain diseases, consulting their panel doctors, and so allowed these diseases to be much more serious owing to lack of proper treatment.—Lord E. PERCY replied: In reply to the first part of the question I would refer the hon. Member to the report of Sir Humphry Rolleston's Committee which was presented to Parliament. (Cmd. 836 of 1920.) The keeping of records is part of the terms of service of insurance practitioners, and is not separately paid for. Great care is taken to preserve their confidential character, and my right hon. friend has no evidence in support of the suggestion contained in the last part of the question.

Revision of Panel Practitioners' Conditions.

Mr. HURD asked the Minister of Health what had been the result of the revision of service of panel doctors under the National Health Insurance Acts which he recently announced; what change was to be made in the number of persons permitted to be on the doctors' panel lists; and what other changes were in view to meet recent allegations of the inefficiency of the system.—Lord E. PERCY replied: The first part of the question seems to indicate some misapprehension. The situation is that certain proposals for the revision of the terms of service of insurance practitioners based mainly on recommendations of the Insurance Consultative Council have been discussed with the Insurance Acts Committee of the British Medical Association, and that committee have themselves put forward certain suggestions. All these proposals will be discussed this week at a conference of representatives of panel committees throughout the country. Pending the result of the negotiations my right hon. friend can make no statement as to possible changes in the service.

Insured Persons and Dental Treatment.

Mr. SCRYMGEOUR asked the Minister of Health whether, as ill-health of the workers was, according to the view of welfare supervisors, considerably attributable to neglected teeth, the Minister of Labour would consider the proposal of extending the national health insurance benefit for dental treatment.—Lord E. PERCY replied: The payment of the whole or part of the cost of dental treatment is included amongst the additional benefits which an approved society is entitled to provide for its members out of a disposable surplus declared on the valuation of the society, and several societies, with a total membership of nearly 7,000,000 insured persons, already make such provision. My right hon. friend entirely agrees as to the value of this benefit in the interests of the health of the workers, and he hopes that under schemes arising out of the second valuation, which is about to take place, it will be made available for an even larger number of insured persons than at present. There are not, however, funds available for the inclusion of dental treatment amongst the ordinary benefits available for all insured persons.

The Metropolitan Asylums Board.

Mr. GILBERT asked the Minister of Health how many hospitals for epidemic diseases were maintained by the Metropolitan Asylums Board; what was the total number of patients they would accommodate, and how many beds were used during the last three years; what was the total expenditure of this body for the last three years; and what rate was paid by the London ratepayer for the cost of this Board.—Lord E. PERCY replied: Fifteen hospitals for infectious diseases (other than tuberculosis and venereal disease) are maintained by the Metropolitan Asylums Board, and the number of beds therein is 8779. The total number of patients treated during the years 1920, 1921, and 1922 were 40,705, 55,324, and 41,819 respectively. The total net expenditure of the Board during the years ended March 31st, 1920, March 31st, 1921, and March 31st, 1922, was £1,872,013, £2,748,872, and £2,565,233 respectively. A rate of 9½d. in the £ has been levied to meet the expenses of the Board during the current financial year. The hon. Member is no doubt aware that the provision and maintenance of hospitals for infectious diseases form only a part, though an important one, of the work of the Board.

British Empire Campaign against Cancer.

Mr. ALBERT BENNETT asked the Minister of Health whether his attention had been called to the British Empire campaign against cancer; and whether the Ministry is assisting the movement in any way in the provision of funds.

—Mr. NEVILLE CHAMBERLAIN replied: My attention has been directed to this campaign, but the Government is not assisting it by the provision of funds.

THURSDAY, JUNE 7TH.

Pensions for Tuberculosis.

Mr. HANNON asked the Minister of Pensions the number of applications for pensions in respect of tuberculosis which had been rejected in the last six months on the ground that the disease was not attributable to war service; and whether he could see his way to consider, in conjunction with the Minister of Health, the formulation of a scheme for assisting the very large number of unpensioned ex-Service men now suffering from tuberculosis.—Major TRYON replied: During the past six months, four years after the armistice, 1600 first claims to pension for tuberculosis have been rejected on the ground that the disability was neither due to nor aggravated by service and 1100 admitted. As regards the last part of the question, I would point out that my authority is limited to cases in which the disability is due to or aggravated by war service, and I am afraid, therefore, that I am not in a position to adopt the hon. Member's suggestion.

British Policy on Opium Question.

Mr. JAMES BUTLER asked the Secretary of State for the Home Department what was the nature of the proposals recently laid before the Opium Advisory Committee of the League of Nations by the British delegate.—Mr. R. McNEILL replied: The British representative on the Opium Advisory Committee of the League of Nations has not yet rendered any report upon the proposals which he has laid before that body.

Misleading Descriptions of Foodstuffs.

Mr. LAMB asked the Attorney General whether he proposed to institute proceedings against the party or parties responsible for the insertion in newspapers of advertisements containing misleading descriptions of foodstuffs.—Sir D. HOGG replied: If any case is brought to the attention of the Director of Public Prosecutions, in which under the existing law criminal proceedings could be instituted, the matter will be carefully considered by him. I have submitted to the Director the advertisement which my hon. friend was good enough to show me, but he advises me that it does not offend against the criminal law. The usual method of checking misleading descriptions of foodstuffs—whether advertisements or not—is by proceedings under the Sale of Food and Drugs Act, 1875, and the administration of this Act is almost invariably left to the local authority concerned.

Presumption of Disability.

Mr. FREDERICK ROBERTS asked the Minister of Pensions whether in the first annual report of the Minister of Pensions it was stated that in respect of tuberculosis it was agreed, following the French system, that the general presumption should be that the disease was in some way connected with the man's service, unless there was evidence to the contrary; whether the acceptance of presumption in cases of other disabilities due to war service was a matter of departmental regulation; and whether he would issue instructions that disabilities should be accepted as due to war service, unless the Ministry was able to prove the contrary.—Major TRYON replied: In the case of men invalided from service it is an express rule of my department that there is a prima facie presumption that the invaliding disability is due to or aggravated by the man's service. In the case of demobilised men, I have, in accordance with the advice of the highest independent medical authorities in the Kingdom, directed, in the case of certain diseases, of which the first overt symptoms may not appear for some time after the original causation of the disability, that even though such symptoms do not manifest themselves until a year (in the case of tuberculosis), or, in the case of certain other diseases, even two years after the man's discharge from service, the disease may, subject to proper diagnosis of the man's condition, be accepted as having originated in or existed during service, without further evidence on the point. I am medically advised, however, that these principles could not apply to any and every complaint from which an ex-Service man may suffer for the rest of his life, for the reasons which I gave in an answer on April 19th.

Cancer Research.

Sir JOHN LEIGH asked the Minister of Health what action had been taken during the last three years by his department to assist in cancer research; and what public funds had been expended for this purpose.—Mr. NEVILLE CHAMBERLAIN replied: I would refer to the answer given on this subject to the hon. Member for Lincoln on the 4th inst., to which I may add that the average amount devoted by the Medical Research Council to direct cancer research has been approximately £5000 during the last three years.

MONDAY, JUNE 11TH.

Advertisements on Medical Certificates.

Colonel Sir ARTHUR HOLBROOK asked the Minister of Health whether he was aware that advertisements were being printed on the back of medical certificates granted in connexion with the National Health Insurance; and whether he would take some action to relieve medical officers of acting as advertising agents for foodstuffs of which they may disapprove.—Lord E. PERCY replied: I would refer the hon. and gallant Member to the reply given on May 16th by Major Boyd-Carpenter to the right hon. Member for Derby (THE LANCET, May 26th, p. 1085).

Sir H. CRAIK: Has the hon. gentleman received from the medical practitioners a very strong protest against this, and the suggestion that the space used for advertising a certain sort of foodstuff might be applied with greater advantage?

Lord E. PERCY: Yes, we have received it.

Sir H. CRAIK: Has it been considered by the Ministry?

Lord E. PERCY: Yes, Sir.

Miners' Nystagmus.

Mr. MARDY JONES asked the Secretary for Mines whether his attention had been drawn to the dissent of Mr. Frederick Robson from the findings of the Medical Research Council, as expressed by him in a paper he read recently before the South Wales Institute of Engineers, as to the cause of miners' nystagmus, in which paper Mr. Robson gave evidence in support of his theory that miners' nystagmus was caused by the inhalation of noxious gases given off in the coal-face and not to the defective illumination of miners' lamps as given in the findings of the said Council; and, in view of the character of the evidence submitted, if he would institute further inquiry into the whole matter.—Lieut.-Colonel LANE-FOX replied: I have seen Mr. Robson's paper. The evidence in support of his theory has been considered carefully by the four doctors who constitute the Council referred to, and they are, unanimously, unable to accept that theory. I appreciate that Mr. Robson has devoted much time and care to the study of nystagmus, and every theory supported by evidence should be considered. This has been done by a body of whose authority there can be no doubt, and I see no reason for instituting any other inquiry than that which has been entrusted to the Council.

The Opium Evil in China.

Dr. CHAPPLE asked the Under Secretary of State for Foreign Affairs if he would ascertain from our representatives in China whether there was any evidence that the habit of opium-smoking was lessening in certain places and amongst certain peoples in proportion to the spread of the habit of cigarette-smoking; and whether he would take steps to test the feeling amongst Powers interested in China in favour of a tobacco monopoly that would serve the double purpose of placing Chinese finances on a stable footing and of counteracting the opium evil.—Mr. R. MCNEILL replied: I have never heard of any evidence in support of the theory advanced in the first part of the hon. Member's question, but His Majesty's Minister at Peking will be asked to furnish a report. In regard to the second part, there is already in existence at Peking a Wine and Tobacco Administration charged with the control of the taxation of tobacco and cigarettes throughout China. Apart from treaty and other obligations to the creation of monopolies, it may be found that better results can be reached by the strengthening of this administration than by the establishment of a new organisation.

International Congress against Alcoholism.

Lieut.-Colonel JAMES asked the Under Secretary of State for Foreign Affairs whether an invitation had been received from the Royal Danish Government for a delegation to attend an international congress against alcoholism to be held in Copenhagen in August; whether the invitation had been accepted; and whether it was proposed to defray the cost out of public moneys.—Mr. R. MCNEILL replied: The answer to the first and second parts of the question is in the affirmative. In reply to the third part of the question, it is not anticipated that any expense, chargeable on public funds, will be incurred.

TUESDAY, JUNE 12TH.

Opium Traffic Control.

Sir WALTER DE FRECE asked the Secretary of State for the Home Department what were the practical results of the meeting of the Advisory Committee on the Opium Traffic at Geneva, more especially in regard to the manufacture and distribution of drugs.—Mr. BRIDGEMAN replied: The main results of the meeting, I understand, were (1) that an agreement was reached with the delegation from the United States Government which will, it is hoped, have the effect of securing coöperation between that Government and the

States which are members of the League in the work of giving full effect to the International Convention of 1912; and (2) that the Advisory Committee decided to make recommendations for the adoption, by agreement between the powers interested, of measures for securing a more effective application of Part II. of the Convention which relates to the suppression of the use of opium for smoking, and a limitation of the manufacture of morphine, heroin, and cocaine, and of the production for export of the raw material from which the drugs are made.

Medical Benefit for Dependents.

Mr. TILLET asked the Minister of Health whether, seeing that there was no provision in the Health Insurance Act for medical benefit to mothers and wives of insured persons who were acting solely as housekeepers to their family, he would introduce legislation in order to provide such benefit.—Lord E. PERCY replied: As the provision of medical benefit for these dependents of insured persons would necessitate a substantial increase in the present weekly contributions, my right hon. friend does not think the present time opportune for the introduction of legislation to the effect suggested.

Medical Work in Native Reserves.

Sir ROBERT HAMILTON asked the Under Secretary of State for the Colonies the total estimated revenue for the current year, both direct and indirect, attributable to the African population of Kenya, and the total amount voted to be expended in the native reserves on medical, educational, and economic objects for the benefit of the African population.—Mr. ORMSBY-GORE replied: The total estimated revenue for the current year attributable to the African population of Kenya is approximately as follows: direct, £501,000; indirect, £219,000. The estimated expenditure during the year in the native reserves or for the benefit of the native population under the heads indicated cannot be stated, as the Colonial estimates do not, and indeed cannot, show what part of the total vote under each head is to be regarded as money expended for the benefit of one particular part of the population. Specific provision, however, is made for £21,321 for expenditure on native education, while for medical work in native reserves (apart from the provision for native hospitals and the personnel and material of the medical department, which is provided for the needs of the whole community) provision of £8074 is made. It is not possible to estimate the proportion of the Government's expenditure on economic services which is attributable to native purposes.

WESTMINSTER HOSPITAL: TEMPORARY CLOSING.—

Owing to the necessity of carrying out extensive repairs and alterations, Westminster Hospital will be closed for in-patients from July 2nd next for about six months. Out-patients will be treated at Westminster Hospital Medical School, 12, Caxton-street, but no casualty cases will be dealt with. Substantial improvements will be made in the wards and in the out-patient department, an additional operating theatre will be built, the X-ray, massage, and other departments will be brought up to date, and better accommodation for the nurses will be provided in a home outside the hospital. The cost is estimated at about £45,000, for which a special appeal will shortly be made.

JUBILEE OF WIGAN INFIRMARY: A TRIBUTE TO THE VOLUNTARY SYSTEM.—

On June 4th Lady Mary Lindsay, daughter of the Earl of Crawford, in the absence of her mother, unveiled a commemoration tablet in connexion with the new operating theatre which is in course of construction in the infirmary grounds. Lord Crawford, in opening the proceedings, said that even if there were no other reason, the remarkable financial status of this infirmary marked it out as one of the most notable institutions of the kind in Great Britain, and that financial status was based upon the system of weekly contributions, an excellent movement justified by its results. Last year the income from these weekly contributions amounted to the gigantic sum of £17,000. Mr. J. A. Parkinson, M.P., said it was only by the voluntary system that they got the best out of people, and it was only by voluntary effort they might hope to achieve perfection in hospital economy and progress. Hospitals of this kind were the institutions they should do their very best to help forward, and he had no hesitation whatever in appealing to the people present, and those who were absent, to help the infirmary in every possible way.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, W.

THURSDAY, June 21st.—4.30 P.M., Dr. F. F. Blackman: The Croonian Lecture: Plant Respiration as a Catalytic Process.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, June 19th.

SPECIAL GENERAL MEETING OF FELLOWS: at 5 P.M.

Thursday, June 21st.

DERMATOLOGY: at 5 P.M. (Cases at 4.30 P.M.)

Demonstration:

Sir Archdall Reid: A New Method of Treating Skin Diseases.

Cases:

The following will be shown: Dr. H. W. Barber: Scleroderma associated with Vitiligo. Dr. S. Ernest Dore: (1) Neurofibromatosis (two cases); (2) Parakeratosis Variegata.

Other cases will be shown.

Friday and Saturday, June 22nd and 23rd.

STUDY OF DISEASE IN CHILDREN: Provincial meeting at Bristol.

Friday, June 22nd.

2.30 P.M.—Meeting at the Bristol Children's Hospital.

4 P.M.—Meeting at Bristol University, Department of Pathology.

7.30 P.M.—Dinner at Hort's Restaurant, Mr. F. Richardson Cross in the chair.

Saturday, June 23rd.

9.20 A.M.—Visit to Mr. Vesey's Farm, Wincanton. (For details see special circular.)

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W. 1.

THURSDAY, June 21st.—7.45 P.M. to 8.15 P.M., Annual General Meeting. Dr. L. F. Hirst: Microscope Specimens. Colonel C. Lane will show an ordinary centrifuge with buckets adapted for direct centrifugal flotation for use in the diagnosis of ankylostome infestation. The Chalmers Memorial Medal and the Manson Medal will be awarded, and Dr. Hirst will read a paper on the Spread of Plague in the East Indies.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE POST-GRADUATE LECTURES, 1, Wimpole-street, W.

FRIDAY, June 22nd.—5.30 P.M., Sir S. Russell-Wells: Circulatory Differences between Mitral Stenosis and Aortic Regurgitation.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, June 18th.—12 noon, Mr. Simmonds: Applied Anatomy. 2.30 P.M., Dr. Saunders: Medical Wards. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10 A.M., Dr. Drummond Robinson: Gynaecological Operations. 11 A.M., Mr. McDougall: Electrical Dept. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.

WEDNESDAY.—11 A.M., Mr. Simson: Gynaecological Demonstration. 2 P.M., Dr. Burnford: Medical Wards. 3 P.M., Dr. Pernct: Skin Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Bishop Harman: Eye Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 2 P.M., Mr. Banks-Davis: Nose, Throat and Ear. 3 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Nose, Throat and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham, S.W.

FRIDAY, June 22nd.—4.30 P.M., Mr. V. Z. Cope: Demonstration of Surgical Cases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

Lectures at 4.30 P.M.

MONDAY, June 18th.—Dr. A. J. Whiting: The Polygraphic Study of Heart Disease.

TUESDAY.—Mr. J. Bright Banister: Heart Disease in Pregnancy.

WEDNESDAY.—Dr. J. Browning Alexander: The Scope of Rectal Alimentation in Modern Treatment.

THURSDAY.—Mr. H. W. Carson: Pelvic Peritonitis.

FRIDAY.—Mr. E. Gillespie: Hæmaturia.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, June 18th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Clinical Lecture: Dr. Aldren Turner.

TUESDAY, June 19th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Tumours causing Compression Paraplegia: Mr. Armour.

THURSDAY, June 21st.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Encephalitis: Dr. Grainger Stewart.

FRIDAY, June 22nd.—2 P.M., Out-Patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Labyrinthine Tests: Mr. Scott.

COURSE OF LECTURES ON NEURO-PATHOLOGY.

MONDAY, June 18th.—12 noon, Syphilis of the Nervous System: Dr. J. Godwin Greenfield.

A COURSE OF 12 LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on TUESDAYS AND FRIDAYS if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the whole Course is £12 12s., including Anatomy and Physiology, but these Lectures may be taken separately for a fee of £4 4s. The fee for the Course without Anatomy and Physiology Lectures is £10 10s. Special arrangements as to fees will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

WEDNESDAY, June 20th.—4.15 P.M., Dr. W. M. Feldman: The Physiology of the New Born.

FRIDAY.—4.15 P.M., Mr. G. E. Neligan: Hydronephrosis.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, June 19th.—5 P.M., Clinical Meeting. 6.30 P.M., Fellows' Monthly Dinner at Cavour Restaurant, Leicester-square.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, West Smithfield, E.C.

TUESDAY, June 19th.—5 P.M., Dr. Andrew Balfour: Tropical Hygiene (3).

THURSDAY.—5 P.M., Tropical Hygiene (4).

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, June 21st.—4 P.M., Mr. Addison: Cleft Palate.

INFANTS HOSPITAL, Vincent-square, S.W. 1.

TUESDAY, June 19th.—8.45 P.M., Dr. B. Shires: X Ray Findings in Pathological Conditions of the Bone.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, June 21st.—5 P.M., Dr. J. B. Banister: Ante-natal Examinations.

SALFORD ROYAL HOSPITAL, MANCHESTER.

TUESDAY, June 19th.—6 P.M., Mr. Robert Ollerenshaw: Diagnosis and Treatment of Injuries in the Region of the Elbow-joint in Children.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

MONDAY, June 18th.—At Hereford, Mr. H. Chitty: Infantile Paralysis; Etiology; Stages; Prevention of Deformities.

Appointments.

GREER, W. N., M.B., Ch.B. Edin., has been appointed Third Assistant Medical Officer, Leeds Township Infirmary.

HINDS, F. W., M.B., B.Ch. Belfast, House Surgeon, Whitehaven and West Cumberland Infirmary.

Jessop Hospital for Women, Sheffield: COCKER, DORA, M.B., Ch.B. Sheff., and PINDAR, DORIS, M.B., Ch.B. Sheff., Assistant House Surgeons.

Certifying Surgeons under the Factory and Workshop Acts: DOYLE, J. L., M.B., B.Ch.N.U.I. (Abercraive); PEEL, H. G., L.S.A. (Sherburn, East Riding).

Medical Referees under the Workmen's Compensation Act: CAMPBELL, D. B., M.B., C.M. Glasg. (Kilmarnock District and the Isle of Arran); MCINNIS, A., L.R.C.P. & S. Edin. (Dumbarton District).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Mental Hospital.—Jun. Asst. P. £250 to £350.

Birmingham and Midland Eye Hospital.—H.S. £120.

Blackburn County Borough.—Asst. M.O.H., &c. £600.

Bradford Municipal General Hospital, St. Luke's.—H.P. and H.S.

Each £200.

Brighouse Borough, &c.—M.O. and School M.O., &c. £750.
 Cairo, Kitchener Hospital for Women.—Female Res. M.O. £E.400.
 Cancer Hospital, Fulham-road, S.W.—H.S. £100.
 Cardiff Royal Infirmary.—Cas. Surg. O. £100.
 Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.
 Charing Cross Hospital Medical School, W.C.—Pathological Chemist. £400.
 Chesterfield and North Derbyshire Royal Hospital.—Cas. O. and Orthopaedic H.S. £170.
 Colchester, Essex County Hospital.—Hon. Pathologist.
 Durham County Council Maternity and Child Welfare.—Asst. Welfare M.O. £600.
 East London Hospital for Children and Dispensary for Women, Shadwell, E.—Afternoon Cas. O. £120.
 East-street Welfare Centre, 153a, East-street, Waltham, S.E.—Hon. Clin. Assts. Hon. P. for Infants.
 Elizabeth Garrett Anderson Hospital, 144, Euston-road.—Jun. Asst. Pathologist. £100.
 Grimsby and District Hospital.—Sen. H.S. and Jun. H.S. £175 and £125 respectively.
 Grosvenor Hospital for Women, Vincent-square, S.W.—Hon. Reg. India, Countess of Dufferin's Fund.—Two Medical Women. Rs.550 per mensem.
 Lancashire County Mental Hospital, Winwick, Warrington.—Locum Tenens. 7 guineas weekly.
 Leicester City.—Maternity and Child Welfare M.O. £500.
 Liverpool Royal Children's Hospital.—Res. M.O. £150.
 Manchester Children's Hospital.—Asst. S. £50.
 Manchester Northern Hospital for Women and Children.—H.S. £200.
 Manchester Royal Infirmary.—Asst. Surg. O. £35.
 Margate, Royal Sea Bathing Hospital.—Res. S. £200.
 Metropolitan Ear, Nose, and Throat Hospital, 2, Fitzroy-square, W.—Senior Clin. Asst.
 Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Asst. in Electric Dept.
 North Riding of Yorkshire County Council Education Committee.—Asst. Sch. M.O. £500.
 Nottingham County Sanatorium.—Asst. Res. M.O. £375.
 Oldham Royal Infirmary.—H.S.'s. Each £200.
 Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Two Asst. Res. M.O.'s. £80.
 Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. Cas. H.S. £100.
 Reading, Royal Berkshire Hospital.—H.P. and H.S. Each £200. Also Hon. S. to Ophth. Dept.
 Royal College of Surgeons of England.—Examiner in Dental Surgery.
 Royal London Ophthalmic Hospital, City-road, E.C.—Three Refraction Assts. Each £100.
 Sedburgh School, Yorkshire.—M.O.
 Shanghai Municipal Council, Public Health Dept.—Radiologist. Taels 700 per mensem.
 Sheffield, South Yorkshire Asylum.—M.O. £400.
 Shrewsbury, Royal Salop Infirmary.—H.P. £160.
 South Shields, Ingham Infirmary.—Jun. H.S. £150.
 Swansea General and Eye Hospital.—H.S. £200.
 University College Hospital, Gower-street, W.C.—Surg. Reg. £250. Hon. M.O. in Ear, Nose, and Throat Dept.
 Victoria Hospital for Children, Tile-street, Chelsea, S.W.—H.P. £100.
 West London Hospital, Hammersmith-road, W.—H.P., H.S., and Aural H.S. Each £100. Also Asst. Anesth. and Hon. Med. Radiologist.
 Wolverhampton and Staffordshire General Hospital.—Res. Surg. O. £250.
 The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Egham, Surrey; Rawtenstall, Lancs; Polmont, Stirlingshire.

Births, Marriages, and Deaths.

BIRTHS.

HORGAN.—On June 4th, at Lisbon, the wife of David St. Helier Horgan, M.B., D.O. Oxf., of a daughter.
 TINDALL.—On June 5th, the wife of Dr. R. Tindall, M.C., Chatwin House, Hurworth-on-Tees, Darlington, of a son.

MARRIAGES.

BOOTH—SYMONS.—On June 5th, at St. Mary Magdalene's Church, Bradford, Maurice Dalby Booth, A.C.A., to Mary Irene Symons, L.R.C.P., M.R.C.S.
 GRIFFITH—TRAFFORD.—On June 5th, at St. Nicolas' Church, Guildford, Edward Fyfe Griffith, M.R.C.S., L.R.C.P., to Mary Leigh, younger daughter of Mr. and Mrs. Cyril Trafford, of Withnoe, Guildford.
 McLUSKIE—DAY.—On June 7th, at St. Mary Abbots, Kensington, Peter McLuskie, M.B., to Dorothy Adelaide, elder daughter of Mr. and Mrs. H. Cooper Day, Holland Villas-road, Kensington, W.

DEATHS.

SANDISON.—On June 8th, at Maidenhead, the result of a motor accident, Joseph Hamilton Mundell Sandison, M.D., of The Cottage, Burton-on-the-Water, Gloucestershire.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

PUBLIC HEALTH IN COLOMBO.*

THE sanitary condition of Colombo was seriously affected during 1921 by the very deficient rainfall, which amounted to only 53.56 inches, compared with the annual average (14 years) of 78.91 inches.¹ This extreme deficiency could not but have a serious effect on the sanitary condition of the town, a great part of which is low-lying and flat. The gradients of the drains are very low, and the normal rainfall is necessary for their proper flushing. Moreover, enormous numbers of mosquitoes breed in the catchpits and gullies, canals become stagnant and foul, and swamps dry up, leaving mosquito-breeding pools. The population at the census in March was found to be 244,163, showing an intercensal increase of only 11 per cent., as compared with 33 per cent. during the previous intercensal period. Colombo depends to a large extent on the influx of immigrants for its increase in population; these formed 81 per cent. of the inhabitants at the 1911 census; the diminution in the usual increase was apparently due chiefly to the economic depression which resulted from (a) the war, (b) failure of the imported rice supplies, and (c) slump in the rubber trade. Dr. Marshall Philip, medical officer of health, who presents this report, considers, however, that "a return of the economic conditions to normal will be accompanied by an influx of immigrants, and a consequent increase of population, which in turn will cause the death-rates to appear fallaciously high."

Birth-rate and Death-rate.

Of the total inhabitants of the town, 114,600 were Sinhalese, 54,153 Tamils, 39,692 Moors, 14,863 Burghers, and 2836 Europeans. The density of population in the 11 wards varied from 11.3 per acre in Fort Ward and 12.9 in Wellawatta, to 94.8 in San Sebastian and 118.6 in St. Paul's. The birth-rate, 35.7 per 1000, showed a remarkable increase on the average for 1911-20, which was 24.7; this is attributed to "a marked influx of young adult population, which in turn no doubt resulted from an improvement in the economic conditions." The increase was most obvious in the case of the Sinhalese and Malays, for whom the ratios were 46.9 and 51.1, as compared with 30.5 and 39.3 in 1911-20. In the several wards of the town the ratios varied from 1.5 in Fort Ward and 4.2 in Pettah to 28.4 in Maradana and 30.4 in Kotahena; 2614 births in hospital, not allocated to any ward, bring up the average for the whole of Colombo to 35.7 per 1000. The total deaths numbered 8169, giving a crude death-rate of 33.5, compared with 29.1 in 1920 and 30.0 for the decennium; deducting 1130 deaths in hospital of non-residents, the corrected ratio becomes 28.8, practically the same as that of the preceding year (29.0). In the various wards the crude ratio ranged from 10.4 in Pettah and 11.9 in Fort, to 28.1 in St. Paul's and 30.6 in New Bazar; but on applying the correction for deaths in hospital Fort Ward has the lowest ratio (13.4), and New Bazar the highest (37.7). The "expectation of life" in the last-named ward is therefore little more than one-third of that for the dwellers in the Fort. It is obvious that climatic conditions have little to do with this enormous difference, which is due chiefly to the presence (or absence) of sanitation. With regard to racial variations, and after applying the correction for non-residents, the Sinhalese mortality was 29.0, that for Tamils 27.3, for Moors 30.6, and for Europeans 11.4 per 1000.

Infantile Mortality.—Infectious Diseases.

The infantile mortality (240 per 1000 births) showed a slight improvement on that for the decennium, 1911-20, which was 252, though somewhat higher than in the previous year (233); in Wellawatta ward it was only 192, while in St. Paul's the ratio was 457, and in Pettah actually 500. No climatic considerations can sufficiently account for such an enormous difference. Among the various races that make up the population, Sinhalese (forming the majority) had a ratio of 194, Tamils 386, Burghers 164, and Europeans 60 per 1000 births; the most frequent causes of death were convulsions (69), and atrophy and debility (67 per 1000).

As to infectious diseases generally the report may be considered to be most satisfactory on the whole. There was not a single case of cholera, or of scarlet fever, or of typhus; and only 15 of small-pox, three of these being Port cases, not arising in the town. Of the notifiable infections, numbering in all 3071 cases in Colombo itself, phthisis with 1367 cases was by far the most prevalent, chicken-pox coming next with 711, and enteric fever third with 398 cases. Pneumonia caused 950 deaths (3.89 per 1000), Malays (4.93)

* Government Press, Colombo. 1922.

¹ Mr. Blanford, in his "Climate and Meteorology of India and Ceylon," gives 57 inches, in 1874, as the least fall registered during 17 years' observations.

and Sinhalese (4.34) suffering most; for Europeans the mortality was only 0.97. From phthisis the death-rate was 3.02, Malays (4.42), and Sinhalese (3.68) again being most affected. Influenza caused only 191 deaths (0.78 per 1000), the deadly pneumonic type being conspicuously absent. Diarrhoea, enteritis, and dysentery combined caused a death-rate of 3.41, ranging from 1.29 in Europeans to 5.10 in Malays. There were 572 notifications of enteric fever, 219 resulting in death; in the previous year the cases and deaths had numbered 879 and 338; the improvement has been most satisfactory. The case-incidence for Colombo as a whole and for all races was 2.34, and the death ratio 0.90 per 1000; for Sinhalese these ratios were 3.34 and 1.26 respectively; for Burghers, 4.12 and 1.23; for Europeans, 4.86 and 1.30; while for Tamils they were only 0.84 and 0.35, and for Moors 0.88 and 0.50. In the different wards the case-rate varied from 0.26 in Pettah (a small ward facing the harbour) to 2.03 in Maradana, where "continued fever" (1.13 per 1000) was also prevalent.

Malaria and Plague.

Except for a localised outbreak in 1903-04 Colombo has hitherto been practically free from indigenous malaria, and until lately a few specimens of *Anopheles fuliginosus* had been the only malaria carriers found. During years of normal rainfall the low-lying land around the town is covered with water, abounding in fish, which prey upon the mosquito. When the floods subside, or do not occur (as was the case in 1921), the water evaporates, leaving shallow pools where mosquitoes flourish. In this connexion Dr. Philip quotes a remark by Dr. Bentley, Sanitary Commissioner of Bengal, to the effect that the shutting out of the periodical floods in a certain area of that province, by building a railway embankment, had resulted in a great increase of malaria, which would require a large expenditure to put it right. Any scheme for flood prevention should therefore "make provision for reclamation, including the prompt and thorough filling up or draining of all pools which may form, and for the periodical flushing of all canals." Dr. Philip also points out the necessity for immediate legislation to prevent mosquito breeding in Colombo itself; this has been repeatedly sought for, but has been long deferred.

There were 184 cases of plague in 1921, of which 170 were fatal, giving a death-rate of 0.70 per 1000, and a case-mortality of 92.4 per cent.; no cases occurred amongst Europeans; among Sinhalese the death-rate was 0.46, among Tamils 0.97, and for Moors 1.25 per 1000. The chief centre of infection was in the Sea Street, Pettah area, "where the disease must now be regarded as endemic." There is little danger of bubonic plague being spread by fleas from man to man, the number of bacilli in the blood being generally insufficient to cause flea-infection. "It has become a common saying in India that the safest place in a plague epidemic is the plague hospital." Septicæmic cases, on the other hand, should be carefully isolated in quarters free from any blood-sucking insect. For rat destruction "the three grains barium carbonate rice-flour bait has been found to be better than all others." There were only 15 cases and four deaths from small-pox, and three of these cases were imported. Infant vaccination has unfortunately fallen off, the deficit amounting to 2562 out of the 8724 births registered; in Maradana ward the births numbered 1634, and the primary vaccinations only 651. A mosquito-proof gully, designed by Mr. Cox, the city sanitary engineer, has been found to be entirely successful; it was introduced in 233 street gullies; of these 70 per cent. were found to be quite free from mosquito larvæ, while in the remaining 30 per cent. structural defects were found, or blocking by rubbish, which prevented the proper action of the arrangement.

Food Inspection and Welfare Work.

In regard to the inspection of food, it is stated that Colombo is much behind the times, and that at least one inspector, properly trained for the purpose, is required. The milk-supply has been unsatisfactory, but special attention has been directed to the matter during the year, and a decided improvement effected; of 897 samples examined 24.5 per cent. were found to be adulterated, as compared with 37 per cent. of 563 samples in 1920. Maternity and child welfare work has been much extended in recent years. The number of confinements attended by municipal midwives has risen from 396 in 1906 to 743 in 1921; but the number of children born and attended (749) is still only 1 in 11½ of the total births. There are 144 schools, public and private, with 24,408 pupils (of whom 16,040 are boys); it does not appear that inspection of the children is carried out, and the condition of many of the schools is said to leave much to be desired in lighting, ventilation, and latrine and washing accommodation.

Research Work.

Dr. L. F. Hirst, municipal bacteriologist, reports that shaving-brushes imported from Japan were found to be

heavily infected with virulent anthrax bacilli; also that 409 of 503 goats examined died of anthrax at the slaughterhouse during the year; but it is not stated how the animals became infected. Of 33,090 rats and other rodents examined for plague, 0.19 per cent. were found to be infected. An important research has been conducted on the cause and prevention of loss of carrying power in the Colombo water mains. It was found that the incrustation took place much more rapidly before than after passage through the Jewell mechanical filters; thus showing that "their utility depends quite as much, if not more, on the oxidation of organic matter and the removal of the precipitated ferric hydrate, as on the straining off of micro-organisms." Dr. Hirst notes the change in type of plague in rats, as well as in man, since 1914; "the change from the septicæmic to the bubonic type seems to be associated with a lowered virulence of the infecting organisms, and a lessened susceptibility of the Colombo rats to plague infection." *Xenopsylla cheopis* is the transmitting flea, not *X. astia*. Dr. Hirst considers that *Pulex hominis* is also a plague carrier, and that its importance has been under-rated.

This most interesting report is accompanied by excellent plans of Colombo and its neighbourhood, showing relative severity of disease incidence, and is further illustrated by some very good photographs.

THE HEALTH OF THE EUROPEAN COMMUNITY IN ASSAM.

THE printed proceedings of the Assam Branch of the British Medical Association at their annual meeting, held at Hallong in January, include an article by Dr. Charles E. P. Forsyth, President of the Branch, on conditions affecting the health of the European community in Assam. Dr. Forsyth describes the duties of tea-garden medical officers as of two main kinds—first, the charge of the labour and Indian establishments on the estates, and second, the care of the European managers and assistants with their families. Prior to the engagement of the young assistant for work in Assam, expert medical examination at home is essential; tuberculosis, any pulmonary or heart affection, and rheumatism "form an absolute bar" to employment in the East. Lately disabilities resulting from wounds have had to be considered, and there have been unfortunate occurrences relating to the overlooking of minor psychoses. Physically the man desiring to work in Assam must be of sound general health, able to stand exposure to adverse climatic influences (excessive heat, excessive rain, &c.), and "of a cheerful optimistic temperament." He may be called upon to endure a marked monotony of life; but an intelligent interest in his work, a reasonable aptitude for games or shikar, and a taste for books will keep him physically fit and mentally alert. Home leave, Dr. Forsyth considers, should be granted every three years, being an essential for the maintenance of health and quality of work.

He is of opinion that companies should not engage married men as assistants, or permit marriage until the completion of a first agreement of five years. Women withstand life in the tropics or sub-tropics much less easily than men, and although the fitness of a wife is not a matter admitting of rules, selection may be exercised with advantage in the choice of nurses and governesses. The strain of life for the woman falls chiefly on the nervous system, no greater prevalence of gynaecological affections occurring in Assam as compared with other places; generally speaking, the more work a woman does, the better her health will be—fortified, of course, by periods spent in the hills under better climatic conditions. Children suffer particularly, however; after the sixth or seventh years of age the risk of physical deterioration and mental detriment is definite. Infants do well in Assam up to 3 years, even without removal to the hills.

The essential points in selecting a residential bungalow are free ventilation with a through draught in every room, plenty of light without glare, a thatched roof to promote equable temperature, and partial mosquito-proofing. Full mosquito-proofing results in stagnation of air and in a false sense of security. Electric light and fans are valuable. Little can be said about food; a certain monotony may be unavoidable, but light, simple, and nutritious diet is advisable. Alcohol "other than a whisky and soda at sundown or with the evening meal" is under ordinary conditions to be avoided. Clothing should be absorbent and such as to ward off chill; Dr. Forsyth believes wool to be unnecessary and undesirable, as favouring the onset of prickly heat. Cold baths are to be avoided; the daily bath should be warm or tepid. Exercise should never be pushed to the verge of exhaustion. The article closes with an observation on malaria. Five grains of quinine given daily under all ordinary circumstances constitute, in Dr. Forsyth's opinion, the optimum prophylactic dose, and he has never known blackwater fever to develop in a person taking this dose regularly and conscientiously.

HEALTH CONDITIONS IN KENYA COLONY AND PROTECTORATE (LATE EAST AFRICA PROTECTORATE).

THE population on Dec. 31st, 1921, was estimated as comprising 9792 Europeans (4801 adult males, 2829 adult females, and 2162 children), 22,504 Indians, 2430 Goans, 9279 Arabs, 675 of miscellaneous races, and 2,348,788 natives. From the medical section of the annual report we quote the following: "Thirteen new appointments of medical officers during 1921 completed the sanctioned staff, and in consequence medical work in the native reserves has been largely increased, and the effect in combating infectious disease as it has occurred has been striking. Public health has been satisfactory, and the close of the year found the whole colony free from any epidemic disease. Plague, which was so prevalent in North Kavirondo in 1920, completely died out in the latter half of 1921. Smaller outbreaks in Kikuyu, South Kavirondo, and Nairobi were promptly dealt with so that the disease did not spread. A systematic campaign of rat destruction has been inaugurated in Kavirondo, which, apart from the consideration of the prevention of disease, will, if sustained, have an enormous effect in the saving of food for human consumption. Smallpox was reported early in 1921 on the upper reaches of the Tana river, and it is estimated that 200 natives died of the disease, but the epidemic was over by April, and there was no further outbreak during the year. Kala-azar was definitely proved in two cases, one a European and the other a native; both were infected in the Northern Frontier District, and both ended fatally; this is the first time this disease has been identified in the country. A European child suffering from pseudo-diphtheria was found to be infected by *Monilia tropicalis* (Castellani), the first time this fungus has been identified here. The various hospitals have been improved with a view to an increase in efficiency with economy. Special attention has been paid to the treatment of venereal disease. Indian candidates for the position of assistant and subassistant surgeons have not been forthcoming. This would be of less importance if facilities existed for the training of Africans for these posts; if possible, an effort will be made in this direction. It is also suggested that, in the place of Government medical officers, district surgeoncies should be established in such centres of European settlement as Nakuru and Eldoret; in these districts whole-time fully-salaried medical officers are at present largely occupied in doing non-Government work, and unfortunately so far the prospects for private practitioners have not proved to be sufficiently attractive. In the Native Reserves territory two permanent buildings at Kisii and Machakos have been completed. Two new centres have been opened at Chuka and Narok. Within two months the daily average number of in-patients was over 100, consisting almost entirely of cases of yaws. At seven out-dispensaries in the Central Kavirondo district, with Kisumu as headquarters, over 3000 patients were treated during the first three months of their existence. At Fort Hall, outside the township, a yaws camp, with accommodation for 100 patients, has been started. In Central Kavirondo an investigation is proceeding into birth-rate and infant mortality problems; the information gained will act as a guide to measures to be taken to prevent the present very large waste of human life."

THE LEBANON MENTAL HOSPITAL.

THE annual general meeting of the Lebanon Mental Hospital, Asfuriyeh, near Beyrout, Syria, will be held at the rooms of the Medical Society of London, 11, Chandos-street, London, W.1, on June 19th, at 3.30 P.M., Dr. E. W. G. Masterman in the chair. Dr. H. Watson Smith, director of the hospital, is now at home on furlough, and will be present to give information. Many improvements have recently been carried out at the hospital, among them the installation of electric light. Lavatories, bathrooms, and washhand basins are in excellent condition, and the stock of patients' clothing is satisfactory. A greatly improved set of attendants and nurses has been obtained, and the service and management are now excellent. Results with patients are described as highly satisfactory: the director holds a weekly class in psychiatry for students from the American University, Beyrout. The laboratory is now completely equipped, and the pharmacy is a great convenience, being placed in the centre of the hospital pavilions. It is supplemented by two rooms, one on the male side and another on the female side, where surgical dressing, examinations, and various forms of treatment are conducted. As regards water-supply, a recently installed pump worked without a single hitch during the whole of the past summer, and the hospital was never without water, although economy in its use is still very necessary, and cultivation and garden work have to stand aside.

TRAVELLING FACILITIES FOR BRITISH STUDENTS IN EUROPE.

IN these days British undergraduates and students may spend pleasant and profitable holidays at a very small cost in European countries which have depreciated exchanges. Apart from the useful and interesting experience to be gained in this manner, students travelling on the continent may contribute largely to the cause of European peace by getting to know and understand the lives, aims, and difficulties of the youth of other countries. An arrangement has been made whereby a representative of the European Student Relief in the principal towns of Europe will find the cheapest accommodation and give all possible information to any British undergraduate or student in vacation time who will give him a few days' warning.

The following are the representatives prepared to give assistance in this manner:—Switzerland: C. Hoffmann, 16 Bd. des Philosophes, Geneva; Austria: D. Grant, Rektoratskanzlei, Universität, Vienna 1; Czechoslovakia: Miss M. Quayle, Studentsky Domov, Albertov na Slupi, Prague II.; Germany: A. W. Bonsey, Tieckstrasse 17, Berlin N. 4; Hungary: R. H. Legate, 8, Museum Korut 6, Budapest; Poland: O. Pederson, Kopernika 41, Warsaw; Greece: D. O. Hibbard, 44, Metropolitan-street, Athens; Estonia: G. F. Robinson, Y.M.C.A., Ruutli ulitza, 7a, Dorpat; Latvia: B. Mitchell, Terbatas iela 4, Riga.

The following persons in countries contributing to European Student Relief will not be able to find accommodation, but will be glad to give what assistance they can:—France: R. Vernet, 93, Boulevard St. Michel, Paris V.; Belgium: J. E. Asterrieth, 85, Neir, Antwerp; Holland: Dr. H. C. Rutgers, Hardenbroek, Driebergen. Headquarters in London: Miss Iredale, General Buildings, Aldwych, London, W.C. 2.

Any student or undergraduate desiring further information is invited to write to Mr. C. P. Blacker, 12, Eldon-road, London, W. 8.

WOMEN'S HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—May we once more through the columns of your paper call attention to the valuable work that is being done by the Women's Holiday Fund on behalf of those whose lives are passed in dismal surroundings and weighed down by heavy responsibilities and anxieties.

It is not sufficiently realised how great are the demands made upon the strength and courage of the working woman, and that she is worn out in the never-ending struggle to maintain merely a decent standard of life. She is a stranger to any form of relaxation or recreation and is seldom, if ever, free from the burden of household cares. As has been truly said: "She combines in one tired personality the careers of mother, wife, nurse, cook, housemaid, bargain-hunter, laundress, and dressmaker." It is not surprising that under such a strain, rendered still more intolerable in many cases by overcrowding, the one on whom so much of the happiness and comfort of the home depends should break down in health or grow stunted in mind and soul. The joy and refreshment which a fortnight's holiday at the seaside or in the country brings to some of these over-tired women is better imagined than described.

Is it too much to ask that all those who enjoy their own holidays regularly every year should send a donation, large or small, to enable the Society, which is in urgent need of help, to send away as many women as possible. The full cost of a fortnight's holiday is under £3. For a mother and baby, for whom a special holiday home is run at St. Leonards, the cost is about £3 10s. All applicants contribute something towards their holiday, being assessed according to their circumstances. Donations will be gratefully received and acknowledged by The Secretary, Women's Holiday Fund, 76, Denison House, 296, Vauxhall Bridge-road, S.W. 1.

We are, Sir, yours faithfully,

A. F. LONDON.
MANUEL J. BIDWELL,
Bp. of Miletopolis.
J. SCOTT LIDGETT.
HELEN A. POWNALL,
Chairman of Committee.

THE MICHELIN GUIDE TO THE BRITISH ISLES, 1923.

THE majority of motorists are so familiar with this excellent guide book to the roads that we need say no more than that the new edition for this year, revised and brought up to date, is now ready, and can be obtained from the Michelin Tyre Co., Ltd., 81, Fulham-road, London, S.W. 3, price 5s.

A Lecture

ON AN

OXIDATIVE MECHANISM IN THE LIVING CELL.

Delivered at St. Mary's Hospital, London, on June 7th.

By F. GOWLAND HOPKINS, D.Sc.,

F.R.C.P. LOND., F.R.S.,

PROFESSOR OF BIOCHEMISTRY IN THE UNIVERSITY OF CAMBRIDGE.

I FEAR that to many, and especially to those whose habits of thought are not chemical, the facts to be put before you must seem technical and remote from medical interests. While this may be the case at the present time, the facts in question bear upon so fundamental an aspect of living processes that sooner or later they must become the concern of the pathologist as well as of the physiologist.

It is never, I think, out of place to urge that the living cell should be thought of as a dynamic, and not a static, system. There is some tendency just now, even on the part of those who have transferred their allegiance from histological studies to studies of colloidal systems, to give descriptions of the cell which are nearly as static as purely anatomical descriptions. The progress of histology is as much to be desired as ever and every essential property of the colloidal state is of urgent interest to the biologist. Let us not forget, however, that the living cell is ever the seat of chemical action. Among the most fundamental of the dynamic chemical events related to life are the oxidations which yield energy to the cell. From the chemical standpoint these oxidations have always had and must continue to have especial interest, because while they ultimately depend upon the influence of molecular oxygen, they are concerned with material which under ordinary conditions do not interact with molecular oxygen. This circumstance constitutes a familiar and fundamental problem of metabolism.

THE IMPORTANCE OF WATER IN BIOLOGICAL OXIDATIONS.

Biological oxidations are always catalysed oxidations. Though our knowledge of the catalysts concerned may be still meagre, it has grown appreciably during recent years. What I am to say has reference to such progress as has been made. Earlier attempts to solve the fundamental problem stated above usually relied upon the conception that molecular oxygen is in some way activated within the cell. One such conception still to the front, and probably justified, is that of the so-called oxidase systems. The essential idea underlying the theory of oxidases is that there exist in the cell in small but effective concentration special substances capable of taking up molecular oxygen in the form of a peroxide. The oxygen thus activated can then be transferred to other substances not themselves directly oxidisable. The description of oxidases is familiar and their functions in the cell are probably limited. I shall, therefore, refer to them only indirectly and briefly at a later point in the discussion.

A very notable advance towards an understanding of biological oxidations was made when it became clear that water plays an important part in the processes involved. The biological importance of the peculiar physical and chemical properties of water come, indeed, to the front from whatever standpoint we consider the dynamics of the living cell. It is well always to remember that living stuff consists to the extent of three-fourths of water. To the teaching of Moritz Traube we owe the first clear suggestion that many oxidations due apparently to the direct influence of atmospheric oxygen are in reality only indirectly influenced by such free oxygen. The direct oxidising agent in these cases is the oxygen of water. Traube's views were perhaps not quite correctly formulated and, superficially considered,

they seemed to contradict the principles of thermodynamics; otherwise their influence would have been earlier and more generally felt. Their later development we owe in large measure to Bach.

To be clear on this matter, we must first realise the fundamental fact that many substances when in aqueous solution, or in contact with water, may undergo oxidation in the complete absence both of air and of molecular oxygen in solution. Such oxidations occur anaerobically. The only possible source of oxygen is the water present. If we inquire more closely into the conditions which make these anaerobic oxidations possible, we shall find that in addition to the oxidisable substance and the water, an agent capable of combining with hydrogen must also be present. The oxygen of water may be induced to change partners if and when, but only if and when, its original associate, the hydrogen, is also provided with a new partner. In other words, in aqueous solutions oxidations may occur in the complete absence of free oxygen, but only in association with reductions occurring simultaneously. Bach speaks of the combined processes in question as "hydrolytic oxidation-reduction processes." When uncatalysed, such processes usually proceed so slowly as to elude observation; but they are peculiarly susceptible to catalysis. The circumstance of significance for us is that the living cell is rich in enzymes capable of catalysing just this type of change with remarkable efficiency.

It will be convenient during further discussion if, in accordance with present usage, I speak of the substance which, in the kind of chemical system we are considering, becomes oxidised by water as the "oxygen acceptor" and of the substance which is simultaneously reduced by hydrogen as the "hydrogen acceptor."

MOLECULAR OXYGEN AS HYDROGEN ACCEPTOR.

It should be called to mind at this point that life is possible without oxygen. In the metabolism of the many parasites which live anaerobically, the maintenance of a supply of hydrogen acceptors is of the utmost importance. It is furthermore quite likely that in more normal forms of metabolism processes of the kind we are considering occur at intermediate stages, and perhaps especially when for one reason or another the contemporary oxygen supply becomes deficient. The point of greatest importance for us to remember, however, is the following: In practically every case of oxidation due to the oxygen of water the hydrogen acceptor, instead of being some product of metabolism, may—whenever it is available—be molecular oxygen itself. Although the fact seems paradoxical, we may have chemical systems, of which the living cell is a conspicuous example, in which atmospheric oxygen oxidises the hydrogen of water, while the oxygen of the latter is engaged in oxidising a dissolved substance. To make the possibility of this appear as logical to the mind many points have to be taken into consideration: first, the nature of the molecular species present in a mass of water (they are certainly not all simple H₂O molecules!); next the nature of the catalytic system involved, and perhaps also the formation of temporary intermediate associations between the water molecules and those of the substance oxidised.

To demonstrate experimentally the occurrence of the chemical events in question, when they proceed anaerobically, a simple and familiar technique is commonly employed. Into a system comprising a preparation from an animal tissue and a substance of which the oxidation is to be studied such an indicator as methylene-blue is introduced. This being a reducible substance acts primarily as an efficient, if artificial, hydrogen acceptor. It also acts, because of its loss of colour on reduction, as a convenient indicator of the progress of events. If, for instance, we make a tissue preparation in such a way that it does not by itself reduce methylene-blue, and this may be easily done by washing the original tissue with water, the addition of this or that substance may restore the reducing power. If it does so we may be sure that

the substance in question undergoes an oxidation which is simultaneous with the reduction of the methylene-blue. I might mention a large number of instances in illustration of the fact that substances are thus anaerobically oxidised by tissue catalysts in the presence of efficient hydrogen acceptors, such as are represented by methylene-blue.

I will content myself with one. Morgan, Stewart, and I have shown that the familiar biological oxidation whereby the purin bases xanthin and hypoxanthin are converted into uric acid can, in the presence of methylene-blue, proceed anaerobically. The enzyme concerned is present in many tissues and, oddly enough, like the Schardinger enzyme which oxidises aldehydes, it is passed by the mammary gland and occurs in milk. In the latter it is very easy to demonstrate its properties and to make quantitative studies of its activity. If air be excluded, milk, of course, does not by itself oxidise the bases; but even under rigidly anaerobic conditions, if methylene-blue as well as xanthin or hypoxanthin be added to the milk, oxidation proceeds apace and uric acid can be afterwards separated from the fluid. The significant fact, however, as I would once more emphasise, is that atmospheric oxygen can take the place of methylene-blue as the hydrogen acceptor. If milk containing either of the purin bases be well aerated uric acid is rapidly formed. It is interesting to remember that the change involved is one most difficult to induce by the use of laboratory reagents which bring about direct oxidations. Since under the influence of a biological catalyst it proceeds rapidly *either* anaerobically or aerobically, and since there is good reason to believe that the same catalyst is concerned in each case, we can hardly escape from the conclusion that in the normal biological production of uric acid the oxygen brought to the tissues does not act directly but indirectly through the agency of water.

When we come to inquire as to the precise chemical mechanism involved in the interesting partition of the constituents of water between two acceptors we meet some gaps in knowledge. Oddly enough, we know less about the nature of the molecules present at any moment in a mass of water under ordinary conditions than about those in many other fluids. We do know, however, as I have already said, that they are not simple molecules represented by the familiar H_2O . Modifications occur which may involve great chemical activity, and with these the oxidising catalyst may have special relations.

A simple view, however, is to suppose that the oxygen acceptor takes up hydroxyl groups while the hydrogen acceptor simultaneously removes hydrogen atoms. If A represents the former acceptor and A' the latter, we get:—

We finish, then, with AO and $A'H_2$, representing an oxidation and a reduction simultaneously accomplished. If A' be oxygen we shall get AO and H_2O , the oxidation of A being the essential and only observed result. Whether we are to consider such events as involving the ions of water or the intermediary formation of additive molecular compounds is not yet clear.

HYDROGEN TRANSPORT.

You must here realise, however, that a view has been taken which, at first sight, seems to make the water molecule of less general significance in the processes we are considering. This view provides a standpoint from which it is specially convenient to consider certain facts which are to form the chief theme of my lecture. All the earlier attempts to explain biological oxidation looked, as I have already said, to the activation of molecular oxygen, by some agency or other, as the essential happening. H. Wieland, however, has advanced the view that we

must look rather to the activation of hydrogen. The activity of a catalyst promoting such oxidations is according to Wieland spent primarily in conferring mobility upon hydrogen atoms contained in the molecule of the substance to be oxidised, so that these are readily transferred to an acceptor which may be atmospheric oxygen. Often, of course, we speak of an oxidation when a molecule suffers no more than a removal of hydrogen. Certain cases of oxidation by the tissues come into this category and allow of simple application of Wieland's view. Many living tissues, or preparations made from them, readily oxidise, for instance, succinic acid to fumaric acid.

This may occur anaerobically when suitable hydrogen acceptors are present in the system, or aerobically when the activated hydrogen becomes oxidised to water. On the other hand, in other and perhaps more significant cases oxygen is itself added to the molecule undergoing oxidation. In Wieland's view this is because hydrogen is activated after water has become associated with the molecule. The oxidation of aldehydes to the corresponding acids is a process powerfully catalysed by agents in the tissues. There is good reason to suppose that the aldehyde is oxidised when in the form of a hydrate.

Here again the process may occur with or without free oxygen. It occurs always if a suitable hydrogen acceptor be present. Even in Wieland's view it should be observed water is the source of the oxygen actually and directly concerned in the oxidation. We may now, however, conveniently speak of the oxygen acceptor alternatively as a "hydrogen donor" (Thunberg), and think of the essential process as one of hydrogen transport.

This conception of hydrogen transport makes easy a discussion of the facts which I am now to put before you. I would commend them to your notice mainly because they relate to an oxidative mechanism present in the living cell which from the chemical standpoint is likely to prove easier of understanding than the still somewhat elusive phenomena of enzyme action.

ACTION OF AN ORGANIC SULPHUR COMPOUND IN LIVING CELLS.

Many of the tissue catalysts responsible for particular oxidations are found to be highly specific and to show the instability common to enzymes. It would seem, however, that in addition to the enzymic systems the cell possesses at least one chemical mechanism, with more general functions, comprising factors which are thermostable and relatively easy to study. So far back as 1908 the suggestion was made by A. Heffter that some organic sulphur compound in the living cell might prove to be responsible for part of the reducing power displayed by animal tissues, which might also, perhaps, act indirectly as an oxygen carrier. It is well known that the *sulphydryl* or *thiol* group, $-SH$, when in certain combinations is spontaneously oxidisable ("autoxidisable"), the substance containing it being converted on exposure to the air into a disulphide.

On the other hand, the disulphide form is easily reducible, so the two forms constitute a reversible system.

Two possibilities seemed to present themselves if such a sulphur compound were in the cell. As in most autoxidations the conversion of the thiol group is likely to be associated with peroxide formation.

So that its spontaneous oxidation might provide active oxygen capable of being transferred to sub-

stances not of themselves autoxidisable. On the other hand, the disulphide form whenever produced might well act as an efficient hydrogen acceptor in the sense I have been discussing. As a matter of fact, most, if not all, living cells do contain such a sulphur compound, and it can be shown to play a significant part in oxidations which occur in the cell.

INFLUENCE OF GLUTATHIONE.

In 1921 I was able to isolate from the yeast cell and from various animal tissues a substance which I have called *glutathione*. It has proved itself to be a dipeptide containing the amino-acids, cysteine, and glutamic acid. It is the cystein moiety, of course, which carries the sulphydryl group, and it is to this that the significant properties of the substance are due. Free cysteine, however, does not and cannot accumulate in the cell, and glutathione subserves the functions I am about to discuss better than free cysteine could do, because both its oxidised and reduced forms are freely soluble. Cystine, the oxidised form of cysteine, is of course exceedingly insoluble.

It is necessary that I should ask you to consider rather closely some of the properties of glutathione in order that you may appreciate its functions in the cell. We need not trouble further about its constitution, save in respect of its sulphur groupings. We may represent the two forms in which it exists by means of simple diagrammatic formula thus:

In the tissues when freshly removed from the body the substance is found to be mainly present in its reduced form. This form is autoxidisable, and the normal oxygen supply from the blood must condition its continuous oxidation. It must therefore be also continuously reduced. It is indeed easy to show by a colour reaction that there are factors in the tissue which are capable of reducing the substance. If a solution of the oxidised form at the hydrogen-ion concentration proper to the tissues be placed in contact with fresh tissue it proves to be rapidly reduced until a definite equilibrium between the oxidised and reduced forms is established. It is essential that these facts should be clear at the outset. In the tissues the -SH is autoxidisable; the -S-S- group becomes reduced. A little consideration will show that the presence of glutathione must therefore involve a continuous transport of hydrogen within the cell. Other facts, proved experimentally, will make the nature of its influence clearer. If fresh tissue—muscle, for instance—be thoroughly washed with cold water, the whole of the glutathione will—inter alia—be removed. The washed tissue will now be found to have lost its original capacity for reducing methylene-blue under anaerobic conditions, and also its capacity for taking up oxygen under aerobic conditions. It no longer “respires.” Now the addition of glutathione in relatively very minute amount restores to a considerable extent the capacity of the washed tissue to reduce and to respire. This is not because the added glutathione acts as combustible material, but because its sulphur groupings act as catalysts.

The situation is therefore this: In the washed tissue are substances quite insusceptible of oxidation under the direct influence of molecular oxygen, which is of course what the cell receives from the blood. These same substances nevertheless freely undergo oxidation when in contact with the molecule of glutathione. How can we picture the mode of its action in this case? We think first of all of a simple transport of hydrogen in accordance with Wieland's conceptions, and the justification for doing so is that when the system reduces methylene-blue there must be such transport, since it is the addition of hydrogen and nothing else which converts the blue compound into its leuco form. We may picture the difference between the anaerobic and aerobic events as being merely that in the latter oxygen becomes the hydrogen acceptor. The process may be represented in the

following diagrammatic scheme, in which X represents a constituent of the tissues and A a hydrogen acceptor, be it such a substance as methylene-blue, or, in another case, oxygen.

The facts justify the following conceptions. The hydrogen is not directly transportable from the tissue to the acceptor, or is only so transported with a velocity too slow for observation. It is, however, readily transported to the -S-S- group of glutathione, and from the -SH group thus formed it is again readily transported to the final acceptor. The oxidised form of glutathione may therefore be termed an intermediate hydrogen acceptor, and the presence of the substance in effect catalyses hydrogen transport. It should be noted that while, on these lines, a tissue constituent would only be oxidised in the sense of losing hydrogen, the essential mechanism remains the same if, as in the more general case referred to earlier, the substance in question first forms a molecular compound with water. It is then the hydrogen of combined water which is transported, while the substance is left combined with oxygen.

The question now arises: Is any enzyme remaining in the washed tissue also concerned in this remarkable transport of hydrogen? Is glutathione to be considered as belonging to the category of substances commonly classed as co-enzymes? It would seem not. If the washed tissue be heated to 100° C. or even submitted to prolonged boiling, its behaviour in the presence of glutathione is only altered in the sense that (owing, I think, to the increased permeability) the velocity of its oxygen uptake when it is aerated is increased. The total amount of oxygen taken up, some 2 litres per kilo of tissue, remains substantially the same. Although therefore many substances, of which some were earlier mentioned, require for their oxidation the aid of highly specific tissue enzymes, there are certainly materials in a tissue, far from unimportant quantitatively, which, with glutathione, form a thermostable system capable of taking up ordinary molecular oxygen, or, if you will, of respiring. I am to-day, unfortunately, quite unable to tell you what these materials as a whole may be. The phenomena have been under study for a short time only, and this particular aspect of the study has proved difficult. I can, however, mention substances of which the oxidation is actively catalysed by the substance glutathione. These are the fats which contain unsaturated fatty acids. In dealing with the oxidation of these fats I must, however, complicate somewhat the relatively simple account so far given of the behaviour and functions of glutathione. I trust I can make matters clear here, because I think the complications referred to really add interest to my story.¹

If what I will now call a thermostable tissue-residue be suspended in, say, Ringer's solution containing a suitable concentration of hydrogen ions, and if the suspension be then shaken in a Barcroft's differential manometer, it will be found that little or no oxygen is taken up. If now oxidised glutathione be added to the system, uptake of oxygen immediately begins and proceeds to the limit referred to above. It ceases, of course, when all the special materials remaining in the tissue preparation are oxidised. If, however, to the above system an emulsion of an unsaturated fat (linseed oil, cod-liver oil, &c.) be added, the uptake of oxygen is greatly increased. With certain qualifications it may be said that the increase is proportionate to the amount of fat added. Now the fat emulsion by itself takes

¹ The facts concerning the oxidation of fats have not yet been published. Prof. Otto Meyerhof, working not with a natural cell constituent but with thioglycolic acid, has found that the thiol group catalyses the oxidation of unsaturated fatty acids.

up oxygen with a velocity which relatively to its behaviour in the above system is extremely small. The tissue alone has no effect upon this velocity. The sulphur compound is essential to the catalysis. There is this complication in the facts, however. The oxidation of the fat is catalysed by glutathione alone, that is, when no tissue preparation is present. Only—and this point is very important—the reduced ($-SH$) form of the glutathione must be present from the first. The reason for this necessity is not far to seek. The fat by itself, unlike the tissue residue, has no power to reduce the disulphide group ($-S-S-$) of the oxidised form. There can in this case, therefore, be no question of the simple hydrogen transport so fully discussed above.

What, then, is the chemical mechanism at work when the unsaturated fats are oxidised under the influence of the sulphydryl (SH) group? It is highly probable that during the autoxidation of the sulphur group an unstable peroxide is first formed, and the oxygen so taken up is, in whole or in part, transferred to the fat. If this be so, those of you who are familiar with accepted views as to the constitution of "oxidase" systems (with which I must not stop to deal) will recognise that glutathione comes near to being the factor assumed to be present in such systems—the factor, namely, which forms with molecular oxygen an organic peroxide. In the case at least of unsaturated fats glutathione acts, however, without the assistance of a peroxidase or its equivalent.

In any case, this constituent of living cells seems capable of playing two parts as a catalyst of oxidations. It may facilitate both hydrogen transport and oxygen transport. To say the truth, this might well be expected from the nature of its active groups and from the reversible nature of the essential changes which they undergo.

DISAPPEARANCE OF THE EFFICIENT CATALYST.

I must not leave untouched one interesting aspect of the facts just mentioned. In the simple system formed by unsaturated fats and reduced glutathione without tissue, oxidation of the former comes always to an end before it is complete. The reason for this is that *pari passu* with the oxidation of the fat the $-SH$ group itself undergoes oxidation. As the $-S-S-$ group which results is not reduced by the fat, the efficient catalyst finally disappears from the system. Note how different is the case when the tissue system, capable of reducing the disulphide group, is also present. Then the $-SH$ group as oxidised is continuously reconstituted and oxidation of the fat continues as long as the reduction continues. We see, then, that the oxidation of a substance involving one type of change (let us say hydrogen transport) may control the oxidation of another substance involving another type of change (oxygen transport). We may recognise here an indication of that correlation and organisation of chemical events which is so characteristic of living tissues. The facts adumbrate, or perhaps even indicate lines on which we can come to understand how in the body the oxidation of fats may depend upon the oxidation of carbohydrates.

Perhaps the matters I have put before you with imperfect exposition and without illustrative demonstrations may prove obscure on first hearing. I shall be content if I leave one impression on your mind. You have had before you a case in which catalysis in the cell is determined by the properties of a relatively simple molecule. The mechanism of this catalysis, if not yet wholly understood, is one which after further study on quite ordinary chemical lines should become clear. Is it not likely in the case of other and more elusive catalysts, such as enzymes, that some simple aspect of molecular structure—something analogous with the active sulphur groups of glutathione—is responsible for their activity? The association with colloidal systems, which is responsible for the apparent instability of such catalysts, however important, may be, in respect of the actual chemical mechanism involved, a secondary circumstance.

MILD SMALL-POX.

By J. H. GARRETT, M.D. DURH., D.P.H.,
MEDICAL OFFICER OF HEALTH, CHELTENHAM.

SOME parts of England have been subject to a new experience within the last months in connexion with small-pox, the disease being of such a character as to require a special title such as that which heads this article. For it is my intention to give to "mild small-pox" a signification to indicate something distinctive and different from "small-pox" as commonly conceived. It is a small-pox that very rarely results fatally, whose symptoms are so feeble as to be commonly overlooked, or are at most indicative of nothing worse than a cold, a bilious attack, or other slight and temporary ailment. The body and spirits are affected so little as to negative the necessity of staying in bed, or even within the house, but for the appearance of a peculiar and persistent eruption on parts of the skin, which sooner or later leads to the discovery of the case to a doctor, who may easily fail at first to recognise it as a case of small-pox.

Recent Recrudescence of Small-pox.

Small-pox of any type had until recently become of such rare occurrence in Britain that a very great percentage of our younger medical practitioners have never had the opportunity of seeing a case. The older practitioners who, like the writer, may have prided themselves upon a greater experience, probably saw their small-pox a long time ago, very likely as long as 20 years, which is too long a time to be serviceable when the disease crops up in a new and unexpected guise. The result of such lapse of time is to give rise to a conservative incredulity in the minds of these older men, and a bias in favour of chicken-pox, begot by numerous bad cases of chicken-pox having been encountered as a commonly recurring experience in their practices, some of which were sent into quarantine at the isolation hospital unnecessarily, as the sequel seemed to show. In connexion with the first cases of mild small-pox met with, the mind is also affected by the argument that there has been no small-pox in the locality. How, therefore, can this be small-pox? The late experience to which I began by referring, however, appears to require an alarm note to be sounded to awaken practitioners to the very likely occurrence of this mild type of small-pox in any part of Britain. In South Yorkshire and Derbyshire the cases that have been recognised total some hundreds, and the disease is spreading and is bound to spread further. It is now occurring in growing numbers of cases in the county of Gloucester, the first case or cases having perhaps been brought down from further north, and the centres of its appearance include some of the most remote agricultural villages as well as the more prominent towns of this county. The connexions of the patients with railways, motor char-a-bancs and other vehicular traffic, and with various public institutions, point clearly to the likelihood of the spread of the disease to all parts, so that every doctor should be expectant of meeting with a case.

Medical officers of health when they hear of cases, or cases that are suspicious of being small-pox, are under obligation to immediately report the matter to the Ministry of Health. This will very likely bring in one of the medical officers of the Ministry. It was Dr. W. Vernon Shaw who came to Cheltenham, and in acknowledging his great assistance to me at the outset, I call the attention of every medical officer to the advantage of being able to consult with a confrère who has been occupying himself in visiting the parts of the country subject to outbreaks of mild small-pox, and has seen numbers of cases of the disease, and noted various circumstances attending the cases, all of which renders him expert beyond a common degree in the diagnosis of such cases and in their discovery. It may be one's fate to become as expert as he, but this will not be at first, and he will be able to

shorten the road to such desirable efficiency. The lessons I thus derived were of great advantage to myself and the town I serve, and I am impressed with the great public use of this department of the Ministry of Health.

An Explanation Sought for the Mildness.

It appears that a considerable experience of mild small-pox has been had in the United States, where its usually benign course, as compared with the expected malignancy of small-pox as formerly known, has led to propositions for a new name for this type of the disease. I believe that experience will negative the introduction of any new word as title, since the evidence of its being all one disease is too potent to admit of a separation; in fact, it would be a fatal policy to consider the very mildest case anything other than small-pox. In the course of experience of any considerable outbreak, evidence will be obtained of the tendency of signs and symptoms to vary within wide limits, and, occasionally, for a case to occur of such severity as to present a very ugly appearance. Even in the same family, presumably according to differences of individual susceptibility, the cases occurring at the same time, and derived from the same source of infection, vary much, the diagnosis of the mildest case being assisted and confirmed by the existence of the one or two cases of much more marked character. A considerable proportion of the cases are, however, of the utmost triviality apart from their power of infecting others to produce further cases, some amongst which will always be of a more decided nature. In following up cases that have occurred through two or three generations of infection, a suggestion arises that the mildness of the case tends to decrease as the number of successive cultures in the human body increases. I am not sure enough of this to insist upon it, and the acceptance of such a theory appears to require some other mode of origin than the invariable derivation of infection from a previous case. But in connexion with an outbreak amongst and in near relationship with the children of a school, the triviality of the originating cases was extreme, whilst the evidence that they were cases of mild small-pox, and that they had infected others with whom they came in most close contact, some to develop marked and unmistakable signs, was undeniable. That cases are derived from previous cases is of easy affirmation, but the denial of any other mode of origin is not authorised by any positive knowledge we possess. This at least can be remembered in reviewing the possible cause of such very mild cases, and sufficient evidence may at length be obtained to establish what is indeed the fact as to their origin.

The popular mind is prepossessed with the idea that small-pox must invariably be marked by a severe illness and a rash of disgusting appearance that leaves the face scarred, if recovery should result. It is not surprising, therefore, that parents and others will not readily believe that they or their children are suffering from mild small-pox when signs and symptoms are as insignificant as they may be. The fact is that small-pox, like other diseases, may occur in any degree of severity, from one diagnostic spot occurring in a watched contact with no perceptible illness at all, up to the worst case that results in speedy death. In past epidemics of small-pox, such as that which happened at Gloucester in 1896, where the recognised cases numbered thousands and the deaths hundreds, it is highly probable, judging from our present experience, that very many cases occurred of the nature of mild small-pox, which were never recognised, but which assisted to extend the direful pest.

Small-pox Modified by Vaccination.

I have been interested, in common with many others no doubt, with the theory of Dr. C. K. Millard, medical officer of health for Leicester, which inveighs against the virtue of a general vaccination as protective against small-pox. Though a thorough believer in the preventive influence of vaccination, he has held

that the value of vaccination is much lessened by reason of being the cause of a number of modified cases of small-pox, occurring in those persons who were vaccinated so long previously as to have lost the total preventive power of vaccination, but who have retained a partial protection which may result in a modified case of small-pox which is likely to be overlooked, and, being infectious, give rise to more cases than if the disease had occurred to a more downright degree in an unvaccinated person. We have now throughout the country a population largely unvaccinated. In my recent experience of mild small-pox, all the juvenile cases were in unvaccinated children or adolescents, whilst the adults who had been vaccinated in infancy, 30 to 60 years previously, got the more definite attacks, which, though still mild, could not be mistaken. In connexion with Dr. Millard's proposition I wish to make it clear that in mild small-pox we have degrees of modification more pronounced among the unvaccinated than anything of the sort that has ever been attributed to previous vaccination, however long ago done. There must also always be a doubt as to whether the modified case occurring in a vaccinated person is a naturally modified case of mild small-pox, or that the modification is due to vaccination. The former appears most likely, and the contemplation of an outbreak of mild small-pox serves, in my mind, to discount almost entirely what Dr. Millard has advanced.

There is evidence here, and everywhere, that recent vaccination has a very powerful and pronounced protective influence against mild small-pox, and what is also very interesting is that mild small-pox exercises as strong a protective influence against after-vaccination. This is easily capable of practical demonstration and has been demonstrated at Cheltenham in a most positive way. Even the more trivial cases of mild small-pox have been promptly rendered exempt from the effect of vaccination, whilst all the brothers and sisters of their families have shown a usual positive result when vaccinated at about the same time, the whole having been previously unvaccinated. Two or three weeks from the first occurrence of the smallest number of eruptive spots of mild small-pox appears to be sufficient time to insure this preventive result against vaccination being obtained. Vaccination and mild small-pox are equally preventive of each other. Previous recent vaccination (say up to seven years) is consequently an assistance in determining a doubtful case as not being mild small-pox. Failure of vaccination after an attack of mild small-pox is confirmatory of the diagnosis.

Contacts and School Closure.

The infectiousness of mild small-pox varies much in different cases. In this it resembles other infectious diseases. We know well that in scarlet fever and diphtheria it is not that all cases are very infectious, but only one here and there. This appears to be the case in a marked degree with mild small-pox, and the severity of signs and symptoms, or the bad appearance of the case, does not of necessity indicate a corresponding degree of infectiousness. Several of the worst-looking cases, though much exposed, have resulted in no further cases that could be traced to them. On the contrary, a case that was of a trivial description, with not more than ten eruptive spots and no recognised constitutional disturbance at all, gave rise at the end of the incubation period after a short exposure to three other known cases. There is distinct evidence that the time when the rash is first appearing is the most infectious stage of the disease. There is evidence also that the infection is more effective the closer and more persistent the contact. At the school the cases tend to be limited to the class. The child infected at school has the greatest effect in producing further cases in its home. Four children of different families who had very feeble attacks of mild small-pox, which did not prevent them going to school whilst infectious, and which in fact resulted in a few other cases in the school, produced 15 cases in their own homes amongst the unvaccinated members. They

At first glance this case deceived the author, the distribution of eruption being mainly on the trunk (the back is shown). Pustules on the feet emphatically corrected the diagnosis.

would be at home of course in any case during the most infectious period, and in very close and continuous contact with the brothers, sisters, and parents. Observation of these and other cases has resulted in the suggestion to my mind of the conveyance of the disease by a parasitic carrier, and I mention the itch mite as a possible medium. Such a beginning of mild small-pox in a school, where the bulk of the children are unvaccinated, the first cases being of this mildest of mild types, is alarming when first contemplated as being the likely mode of origin of an epidemic, whose cases might be much more serious as they advanced than as at first initiated.

The watching of contacts in a large school, including daily visits to all absentees to ascertain the nature of the ailment that may be keeping them from school, is

knowledge and judgment and cannot be left to untrained assistants.

Difficulties of Diagnosis.

The difficulties of certain diagnosis of commencing cases of mild small-pox are most considerable. It is only when occupied in searching amongst absentees from school for possible cases of the disease sought for that you become aware of the infinitude of small complaints to which school-children are subject, many of them accompanied by a rash or eruption which may closely simulate the beginnings of mild small-pox without being it (Fig. 1). Here is where recent vaccination is of such great assistance to immediate diagnosis, and relief of doubt. An undoubted prior attack of chicken-pox in a child is also assisting to exclude the likelihood of that disease, though mere

FIG. 5.

FIG. 6.

an arduous business which would become difficult or impossible to perform when many schools were involved. The policy of closing the schools, under such circumstances, requires the most careful consideration, and must generally be negated, as a more effective control can be exercised whilst the school is running. Very urgent circumstances may sometimes indicate the desirability of closing a small school. But where hundreds of children are involved there is no wisdom in closing the school because a few cases of mild small-pox have occurred in it, for by closing you only scatter your scholars and throw your control to the winds. In the instance I quoted of four scholars attending one school, in whom signs of mild small-pox were discovered after they had had time to infect their families and some few others of their schoolmates, the further spread was controlled by the following cases in the school being picked up at the moment of first definite signs of having contracted the disease, the last being discovered at the end of the third incubation period counting from the first known. But the anxiety and labour involved in connexion with that one school showed clearly how easily the watching-of-contacts method for exterminating mild small-pox might, and must, fail if the whole of the schools of a town became affected. The examination of the children calls for the best medical

hearsay, without evidence by pock marks, of this disease having been suffered is not to be relied upon when it is simply the parent who thinks the child has had chicken-pox. Right recognition of the complaint, as well as clear memory of which child of the family had it, and whether it was not really measles, or something else from which the particular child had before suffered, are points upon which confusion in the mind of a mother with a large family is very likely to occur. But recent vaccination is the all-important thing eagerly inquired about as the sheet anchor of protection, and the settling point in diagnosis, which never seems to fail. Perhaps the conditions of the skin which give rise to most doubt as between them and the beginnings of mild small-pox are itch spots, flea-bites, and other insect bites common in the summer season, acne, chronic and intermittent eruptions of boil-like character, urticaria, local erythemas and other rose rashes, impetigo, temporary eruptions of dietetic origin, and simple eruptions without name, ordinarily passing for nothing of sufficient importance to notice, also chicken-pox (Figs. 2 and 4). Formerly, we have had held up to our view the difficulty and importance of determining between small-pox and chicken-pox, but after an experience which has led to frequent close comparison between these two diseases running concurrently, a

condition of expertness is arrived at which enables a diagnosis to be made with considerable certainty from the second day of the rash, if not from the first, though observation through a longer period of time makes the matter more certain, and this even though the case be one of the more trivial instances of mild small-pox. Of course, there are many cases in which one glance suffices to settle the matter either way. Nevertheless, one-glance diagnoses are bad practice and for security's sake every case should be carefully examined from head to foot.

Differentiation from Chicken-pox.

As between chicken-pox and mild small-pox the distribution of the rash, the appearance of the rash, and the length of the continuance of the spots of eruption without much change are visible factors which decide the nature of the case. Thus the rash of chicken-pox will be mainly observable on the belly, back, and sides, with widely scattered spots upon head, particularly the forehead, and limbs. That of mild small-pox will be chiefly on the limbs, very likely extending on to the wrists, hands, ankles, and feet, even perhaps (and this is most useful evidence) affecting the soles and palms; the rash may be scattered over the body and face as well, especially about the mouth, but is not very likely to extend much up the sides towards the axillæ. In chicken-pox some of the spots will appear as simple vesicles, full of clear fluid, and perhaps of rather large size. These vesicles burst quickly and from the second day begin to dry up into a superficial dark-coloured scale. The eruption, in fact, changes in appearance rapidly. In mild small-pox, the spots at first are small, may appear in red pimples, or as round topped shotty elevations which, if they progress, soon become pustular (Figs. 3, 5, and 6). It is rare to see a papule pass into a clear vesicle and the vesicle into a pustule, as in old classic descriptions. The eruption is pearl-like, as if containing thick non-transparent fluid. Either the papular or vesicular stage may fail to occur, but only small elevations that tend to immediately become purulent. These are often rather deeply seated in the cutis, and are several days in reaching full development, and many more in disappearing. Some of them do not quite reach the actual surface to dry off and be shed there, but disappear very gradually by absorption. Many, however, are at the surface, and their tops dry off and are shed, often, but not always, leaving a purple stain in the skin, which may be still a little raised above the general level, and if it exhibits a central depression, and where the eruption is considerable some such are sure to be observed, the condition is highly diagnostic of mild small-pox in its later stage. Such purple spots may be looked for in children upon the backs of the wrists in particular, and may be observed as late as the end of the fourth week of the attack, or later, but ultimately fade away. It is quite common for a considerable part of the commencing eruption to abort, and never reach a stage beyond minute pimples which die back, or gradually disappear by absorption.

The other chief characteristics of mild small-pox include a comparatively slight constitutional disturbance. At the onset there may be rise of temperature, aching of limbs and head, more rarely of the back, vomiting or nausea, nasal catarrh. The complaint at this stage is likely to be considered a bilious attack, a cold, or influenza. Within two or three days these symptoms subside, and the patient feels better, and perhaps goes out until the rash is first observed somewhere between the third and seventh day from the onset. But in the mildest cases there may be no preliminary illness at all noticeable, and nothing is suspected until the rash appears. Usually some slight illness as that above described precedes the rash, invariably so where the case is marked with much rash. The pock marks, when any occur, are shallow, and tend to disappear. There are few permanent scars, frequently none. After the first symptoms of onset have passed off, most patients are happy in their minds and comfortable, and seem, but for the

eruption, to be in their usual state of health. Termination by death may be said to be rare, and to result only when the disease has advanced to the more serious type.

In a disease of this description, the symptoms being so mild as to result in many of the cases being ambulatory, the difficulty of extinguishing the infection must of necessity be very great should it once become in any degree widespread, and in his efforts to isolate instantly every case as soon as it is discovered the medical officer is much assisted by ample accommodation for isolation in hospital. In this connexion the imperative necessity of wards being apportioned for quarantine observation of doubtful cases must always be borne in mind. Happily, at Cheltenham, at the moment of writing, the incubation period from our last case has elapsed without any case occurring, and the town may be said to be free of the disease. The conditions in the neighbouring town of Gloucester, eight miles away, are, however, less happy, and the menace of re-introduction of the infection here from that source is very considerable.

ETHYL CHLORIDE

AS AN ANÆSTHETIC FOR MINOR OPERATIONS IN CHILDREN.

BY SAMUEL F. ROSE, M.R.C.S., L.D.S. ENG.,
DENTAL SURGEON TO QUEEN'S HOSPITAL FOR CHILDREN,
HACKNEY-ROAD, LONDON, E.; LATE DENTAL
SURGEON, NATIONAL DENTAL HOSPITAL.

THE following notes on ethyl chloride anæsthesia in children are the outcome of my own experiences, extending now over some 18 years, and totalling upwards of 15,000 cases without a fatality. My remarks apply only to the anæsthetic as used for children; at the same time, I am of opinion that for all practical purposes they apply equally well to adults, as has been proved in adult cases under my care. The adult, however, takes nitrous oxide gas much better and more effectively than the child, and this modifies the situation, so that in the present article I prefer to leave sub judice the question of the best minor anæsthetic for the adult.

As is well known, opinions are not all favourable to the use of ethyl chloride; but I cannot help taking the view that unfavourable opinions have been based upon results due to the use of unsuitable or imperfect apparatus or some other easily explainable factor, and that where fatalities have occurred quite special circumstances must have been present, or the administrator or operator have taken unusual risks. My experience has been gained in my capacity as dental surgeon to the Queen's Hospital for Children, where practically all of my cases are out-patients.

In the dental department of a large children's hospital a great deal of extraction has perforce to be done, particularly when, as is the case here, the patients are drawn from slum areas. Among out-patients, at any rate, there has been practically no selection of cases, the anæsthetic having been given to all and sundry, of good physique and poor, of all nationalities, and of ages varying from 18 months up to 14 years, which is the hospital age limit. Many of these children have had pronounced cardiac murmurs, or serious pharyngeal obstruction from tonsils or adenoids, and in countless other ways have not been by any means ideal subjects for any anæsthetic. It was, therefore, most essential that the anæsthetic used should have a large margin of safety, and as ethyl chloride has stood the test so well, this brief résumé may encourage others to give it a trial.

Dental operations of a necessity impose a certain limitation on the anæsthetist; ethyl chloride cannot very well be given while the operator is at work, and in consequence I have had no experience in any endeavour to maintain a patient at an anæsthetic level after the acme has been reached, although a repeated dose, or even a third dose, has often been

given during a lengthy or difficult operation. Sometimes considerable bleeding in the mouth is also a feature that cannot be ignored.

The qualities necessary in a good minor anæsthetic are, briefly, safety, ease of administration, reasonable duration of anæsthetic period, and rapidity of induction and recovery. How does ethyl chloride satisfy the above requirements?

Safety.

With regard to safety, the figures given above speak for themselves. They represent an unbroken series of administrations since 1903 by a long chain of resident doctors of the hospital staff, many of them quite new to the anæsthetic, and in no case specialists. The apparatus used can be understood at a glance; a small rubber bag with one opening only, by which it is connected to a face-piece, a stop-cock intervening. Inside the bag is a clip which holds a piece of sponge, and leading to this a tube down which the ethyl chloride is sprayed, a little plug closing its orifice when the bag is charged. Face-pieces can be had in two or three sizes and are interchanged readily; it is important that the size should conform to the patient. Those unfamiliar with the apparatus cannot do better than refer to any illustrated catalogue of anæsthetic appliances. This apparatus is designed for to-and-fro breathing into the bag only, and this is the method advocated; the older way of breathing with admixture of air I consider obsolete and unsatisfactory, after having given it a fair trial.

The ethyl chloride is obtained in graduated bottles of 60 c.cm., and can be sprayed out by means of a specially designed valve and lever; only one hand is necessary to work it. A good administration gives a very fair margin of complete anæsthesia after the acme is reached and the face-piece removed from 20 to 30 seconds is a usual time—enough in most dental cases in children for all the necessary extractions. A very few breaths suffice to attain full anæsthesia, and it is the most rapidly-acting of those in ordinary use. Recovery is quick, at any rate in children, far quicker than from ether or chloroform, and delayed recovery is uncommon.

The dose sprayed into the bag will vary in children from 2 to 5 c.cm. according to age; the latter amount should be sufficient for a boy or girl aged 13 or 14. If the case is the first—i.e., if there is no residue of anæsthetic left from a previous administration—an extra 2 c.cm. should be put in, but where a number of administrations are to follow each other closely the quantities above will suffice after the first. The extra amount seems to be necessary to produce a preliminary saturation of the sponge, &c.

I hold that the only serious rival to ethyl chloride for our purposes is nitrous oxide; in safety there may be little or nothing to choose between them, but my record of N_2O cases is so much less in number, that I must be content to leave it as a debatable point, merely saying that I have seen no fatalities with either.

Administration.

When we come to administration, even the simplest N_2O apparatus will have difficulties for the inexperienced, and this, as I have invariably observed, leads to considerable waste of gas, and not infrequently to bursting of the supply tube or some other calamity.

In type and duration of anæsthetic period the superiority of ethyl chloride is most manifest. Ethyl chloride anæsthesia is quiet and of a comfortable length, usually with muscular relaxation; N_2O , on the other hand, causes marked and sudden rigidity, opisthotonos, or other contortion, and frequently vigorous screaming, the instant that an instrument is applied. So marked is the difficulty with N_2O that it may be safely stated that, from a dental standpoint, one administration of ethyl chloride will equal three of the former in effectiveness.

Ethyl chloride has one drawback, and so far as I am aware, one only—its odour, which comes as a surprise to the small patients, and may cause struggling or holding of the breath. I think it, therefore, a good plan to spray a little into the bag to

start with, and after a breath or two to add the full dose; this will do much to obviate the natural alarm.

A Typical Administration.

The following is a description of the method followed in my dental clinic. The mother will have been instructed not to give the child any food for about four hours prior to the operation. The child is practically always in a sitting position in the dental chair, but at times—e.g., when wearing certain splints—the lying down position is adopted. A nurse stands in front to control the patient's hands, and restrain any tendency to slip down in the chair as anæsthesia progresses. A gag having first been placed in situ, the anæsthetist with a bottle of ethyl chloride in a convenient pocket now places the face-piece of the apparatus accurately over the child's mouth and nose so as to prevent all leakage. After a breath or two a little ethyl chloride is sprayed down the tube, and finally the full dose, and the tube then closed with the stopper. In good breathers a very few full breaths will suffice, and full anæsthesia is quickly reached. This can be most readily judged by the breathing, which becomes deep, rhythmic, and stertorous; the pupils become fixed and dilated, with loss of reflexes. Generally speaking, after, say, the third stertorous breath, the patient is ready, and a useful period of quiet anæsthesia results.

A point of great importance in administration is the complete exclusion of all extraneous air; a leaky apparatus or an imperfectly adjusted face-piece means a long induction, uncertain and noisy anæsthesia, and embarrassment of the operator by a struggling patient. The anæsthetist will require both hands to hold the face-piece accurately in position, particularly if the patient is restless; frequent removal of one hand for the purpose of testing the eye reflexes is to be deprecated, nor is it necessary after a little experience, as the acme of anæsthesia can readily be noted by the character of the breathing. Generally speaking, the quicker the patient goes under the better the anæsthesia, though this must not be taken to mean that results are proportional to the amount of the dose, nothing is gained, and certain risks are incurred by an overdose.

Difficulties Met with in Administration.

(a) *Holding the Breath.*—This is common with the older children, and though it delays matters a little does not seriously affect the result; as is mentioned above, it may often be avoided by not spraying in the full dose all at once.

(b) *Forward Sagging of the Patient's Head.*—The chin being depressed downwards on the thorax, breathing may be considerably hindered. This may be easily dealt with by the nurse or operator pushing up the chin.

(c) *Laryngeal Spasm.*—This may occur now and then, more particularly if the dose is rather large or has been abruptly administered. Should this happen, the face-piece must be removed until normal breathing has been restored, when one can carry on.

(d) *Syncopal Attack.*—Normally ethyl chloride acts as a cardiac stimulant, and the colour becomes rosy even in the pale; hence, no doubt, its safety. Here and there in the course of many cases syncope may be encountered, readily recognisable by the bluish pallor which supervenes. No alarm need be felt if the breathing continues regularly. Stopping the operation temporarily and inversion of the patient for a few seconds will restore the colour; usually it will then be possible to complete as may be necessary. Further measures are very rarely called for.

(e) *Obstructed Breathing.*—This will be encountered more often; there is a tendency for the tongue to swell or fall back in some cases, and of course there may be adenoids or large tonsils present. Should breathing stop, it is easily dealt with in dental cases by the operator, who, being in front of the patient with the latter's mouth gagged open, hooks the forefinger of the left hand well over the root of the tongue and draws it forward, at the same time pushing up the chin with the right hand; breathing nearly always restarts at once.

(f) *Vomiting.*—Only when instructions as to abstinence from food have been disregarded is vomiting likely to occur during the administration. If blood is swallowed—e.g., in dental or throat operations—subsequent vomiting is unavoidable.

I am of opinion that certain cases of fatality under ethyl chloride could have been prevented by the

prompt freeing of the air passages, as in the simple method described, and would suggest that whenever the operation to be performed permits of it, a dental gag should be placed in situ before administration; the saving of time where it is necessary to assist the patient to breathe being of the utmost importance. The gag used is that known as Brunton's, and acts between the front teeth; it is held in position by an adjusting spring, and is not so easily dislodged as other kinds. Its two pads or cups which engage on the teeth are connected by a hinged arm of rectangular shape, which projects forwards, and is readily swung to one side out of the way when instruments or fingers are placed in the mouth. It must not be confused with any form of gag opened by handles, which latter should, as far as possible, be avoided, as in any but very skilful and careful hands they are apt to do damage. There is a face-piece specially designed for use with the Brunton front gag, which has plenty of room inside it, being shaped to accommodate the arm of the gag; this pattern is invariably used at my clinic.

In this brief account I omit opinions and figures from other sources. No doubt in some cases they might appear to conflict with my own experience. I can only suggest in explanation that practically all my patients have been under the age of 14, and that I am dealing with the closed form of administration only. Within these limits safety certainly seems to lie, whatever may be the case outside them, always provided that the simple precautions given above are observed. The perfect anaesthetic has no doubt yet to be found, but in the meantime ethyl chloride has a great sphere of usefulness for those who know its value.

A SLIDE PRECIPITATION TEST FOR SYPHILIS.

By A. H. PRIESTLEY, M.B. VICT.,
LECTURER IN BACTERIOLOGY, UNIVERSITY OF LEEDS; LATE
BACTERIOLOGIST, PUBLIC HEALTH DEPARTMENT,
UNIVERSITY OF BIRMINGHAM.

In the performance of a large number of Wassermann reaction (W.R.) tests one meets with occasional weak or very weak positive results, some of which are undoubtedly non-specific. In the absence of signs or history of syphilis these reactions are usually disregarded. Nevertheless from the fact that, with the use of cholesterolised antigens, non-specific weak results are obtained even with the most careful technique,¹ it is probable that the positivity of the stronger reactions will sometimes be augmented in a similar manner. To control the cholesterolised antigen tests various modifications of the W.R., to be run in parallel, have been suggested; these being mainly the use of simple tissue extracts without added cholesterol, the use of acetone insoluble lipoids, and alterations of the usual time and temperature of the primary incubation. Where large series of tests are performed there are practical difficulties in conducting two series in parallel by different techniques. What is wanted is a control which is simple and rapid, consistently with accuracy, so that it can be performed at the same time as the W.R. The Sachs-Georgi (S.G.) test, introduced in 1918,⁷ provides a control which has given satisfactory results in the hands of many workers. It has many advantages over the W.R., the chief being the reduction of the reagents, and especially the elimination of the most unreliable reagent, complement. But the length of incubation required—from 7 to 48 hours according to different workers—is a drawback to its use as a routine control.

It was shown by Coca 12 years ago⁸ that the cholera vibrio could be readily agglutinated with anti-cholera serum on a slide by a rocking movement imitating the convection current of the water-bath, and this method has since been extended and elaborated by other workers, notably by Garrow.⁹ Five

minutes on the rocking slide will, in the case of the intestinal organisms, give results parallel with those given by the tube method, though at a slightly lower level. It therefore seemed possible that the same method might be applicable to the S.G. test, and this was found to be the case. Doubtless many have tried this method, but I have seen no published results, and as the method seems a satisfactory and very simple control of the W.R., I venture to present my own findings.

TABLE I.
Five Hundred Sera.

W.R.	Slide S.G.				
	1/40	1/20	1/2 to 1/10	Nil.	Totals.
Strong positive ..	95	6	4 (A)	0	105
Moderate positive ..	8	12	4 (B)	0	24
Weak positive and doubtful ..	1 (C)	3 (D)	29	53 (E)	86
Negative ..	0	2 (F)	38 (G)	245	286

Four Cerebro-spinal Fluids.

Strong positive ..	1	1	0	0	2
Weak positive ..	0	0	1	0	1
Negative ..	0	0	0	1	1

Explanation.—Strong positive W.R. = fixation of 8 or more M.H.D. of complement; moderate positive = fixation of 5, but not 8 M.H.D.; weak and doubtful = fixation of <3 to 5, but not 5 M.H.D.; negative = no fixation or the merest trace.

These parallel tests on the 500 sera can be expressed in another manner (Table II.).

TABLE II.

Dilution giving precipitation.	Complement M.H.D. fixed.								
	30	20	16	12	8	5	3	<3	0
1280	1	—	—	—	—	—	—	—	—
640	—	3	—	—	—	—	—	—	—

5	—	—	—	—	—	2	2	6	13
2	—	—	—	—	—	—	4	3	17
0	—	—	—	—	—	—	25	28	245

On an average therefore:

$$\text{Fixation of } \begin{pmatrix} 20 \\ 16 \\ 12 \\ 8 \\ 5 \\ 3 \end{pmatrix} \text{ M.H.D. corresponds to precipitation at } \begin{pmatrix} 1 \text{ in } 320 \\ 1 \text{ in } 160 \\ 1 \text{ in } 80 \\ 1 \text{ in } 40 \\ 1 \text{ in } 20 \\ 1 \text{ in } 10 \end{pmatrix}$$

Technique.

In Tables I. and II. are given the results of parallel W.R. and slide S.G. tests on 500 sera and 4 cerebro-spinal fluids. In all cases the W.R. has been performed by the technique known as the Rochester Row method,¹⁰ with the addition of a third row of tubes carrying 8 minimum hæmolytic doses (M.H.D.) of complement. Sera fixing 8 M.H.D. were then put up with 12, 16, 20, and 30 M.H.D. The slide is 29 by 5 cm., cut with a diamond into 20 compartments; this allows of four sera with their serum controls being tested in four dilutions at the same time. Those sera which were positive in these dilutions were then put up in higher dilutions to extinction of precipitation. For the volumes of serum dilutions and antigen pipettes of No. 52 Starrett wire gauge were used, one being kept for the serum dilutions and one for the antigen dilution. The sera were put up in drops of neat serum, and dilutions of 1 in 2½, 1 in 5, 1 in 10, 1 in 20, &c., and one drop of antigen dilution added to each except the serum control, which consisted of one drop of neat serum and one drop of saline. For convenience these final dilutions are spoken of as 1 in 2, 1 in 5, 1 in 10, 1 in 20, 1 in 40, &c., though actually they are, according to my calculations, 1 in 1·7, 1 in 4·5, 1 in 9·1, 1 in 18·2, &c. Rotation of the slide, either by hand or by means of

a clockwork device similar to Garrow's, over an angle of 45° on either side of the horizontal, was carried on for five minutes, when the results were read by a watchmaker's lens, and expressed as one, two, or three + according to the size of the flocculi. In the tables one + is taken as the limit of precipitation, though generally a trace was observed in the next higher dilution. The antigen used has been a mixture of alcoholic human heart extract and 1 per cent. alcoholic cholesterol in the proportion of 3 to 2 parts. The same antigen has been used throughout the W.R. tests, but in a different dilution. Bordet's antigen plus cholesterol was tried, but appeared to give no better results than the crude heart extract. Just as in slide agglutination a suspension four or five times the density of that used in tube agglutination is necessary to obtain results that can be easily read, so a much more turbid antigen is required for the slide S.G. than the W.R. With a dilution of 1 in 10 or higher the precipitation is very slight even with high concentrations of

The sera were heated at 56° C. for one hour before testing. I do not think there is any perceptible advantage in this period over the usual half-hour for the W.R., though Dreyer and Ward recommend 1½ hours. A number of sera were tested in parallel by slide and tube S.G.; in the latter the technique of Dreyer and Ward¹² was followed closely, the results corresponding very nearly. With strongly positive sera the "zone phenomenon" is manifested on the slide as in the tube—i.e., the 1 in 2, and 1 in 5 dilutions frequently show less precipitation than the next three to five dilutions.

Analysis of Results.

Of these 500 parallel tests a superficial examination shows agreement in 395 (79 per cent.), and disagreement in 105 (21 per cent.); and of the latter the W.R. yields stronger results than the slide S.G. in 61 (12.2 per cent.), and the S.G. than the W.R. in 44 (8.8 per cent.). Further analysis of the cases shows that in neither of these groups is the one or the

TABLE III.—RESULTS OF RETESTING SERA OF FORTY-SEVEN CASES.

W.R. (M.H.D. of complement fixed.)		S.G. (Dilution giving pre- cipitation.)		Interval in months.	Remarks.
1st	2nd	1st	2nd		
0	0	0 0 5	0 2 5	2½ 1 1	12 cases—9 treated syphilis, 1 doubtful, 2 not syphilis. Old treated case; 2 negative W.R.'s previous to first of tests. Old case; 3 courses before first tests, which succeeded a number of positive W.R.'s. Old case with 2 previous neg. W.R.'s. Old case; no pos. W.R. for over 2 years. Treated case; pos. W.R. 2 months before first tests. No signs, but had syphilitic baby 7 months before first tests; no treatment, but provocative injection before second tests.
3	3	10	5	3	Treated before tests and further treatment between. Pos. W.R. 4 months before first tests.
3	3	10	5	4	Incomplete treatment 3 years ago; further treatment between tests.
8	8	80	20	3	16 years. Treated. Previous pos. W.R.'s.
		80	80	2½	7 years. No treatment till after first tests.
0	3	0	0	2½	2 years. Treated. Long series of weak and neg. W.R.'s.
0	12	0	80	4	4 months. Treated before first tests; provoc. injec. before second.
5	8	5	80	2	Over 1 year. Treated before first tests. Previously 2 pos. W.R.'s.
		20	40	3	2½ years. Several courses; 8 previous pos. W.R.'s. Provoc. injec. before second tests.
		40	40	2	1 year. Two courses; 3 previous pos. W.R.'s. Provoc. injec. before second tests.
3	0	0	0	1	Not syphilis; sent because mother syphilitic. Provoc. injec. before second tests.
		0	0	2	Old case treated before first tests, not since.
		0	0	2½	Not syphilis. Eye case. Provoc. injec. before second tests.
3	3	10	2	2½	Old case; 4 courses. Second test was first neg. W.R.
		0	0	3	3 months. Treated before and between tests.
		10	0	1	Case of diphtheria previously mentioned.
		0	0	3	Not syphilis. Child of syphilitic mother treated before child's birth.
		0	0	2	Not syphilis. Multiple growths of bowel. Provoc. injec. before second tests.
3	0	0	0	1	8 years. Treated (several courses). Many earlier pos. W.R.'s, but last one neg.
		0	0	1	Nothing but history of repeated abortions.
		0	0	4	Not syphilis. Psoriasisoid rash at intervals. No treatment. Provoc. injec. before second tests.
		2	2	4	Nearly 3 years; 4 courses before first tests; further treatment since. Several previous pos. W.R.'s.
		10	0	2½	2 years. Treated. Last 5 W.R.'s all neg. Last pos. nearly 2 years ago.
8	5	80	40	2½	Treated since first tests, not before.
		40	20	2	Chancere shortly before first tests. Treated since.
		80	20	2½	18 months; 2 courses before first tests, 1 between tests. W.R. neg. after first course, but pos. again 4 months later.
16	8	160	40	3	Tertiary syphilis. Treated after first tests.
16	3	40	10	2½	Duration unknown. Treated before and between tests.
16	0	160	20	2½	1 year; 2 courses before first tests, 1 between. W.R. came down after each course, and returned to positive again.
30	5	160	40	2½	6 months. Treated before first tests. No record of previous W.R.'s.

strongly positive sera. A dilution of 1 in 5 appeared to give the best results, the antigen being measured into a dry tube and the salt solution slowly dropped into it from a height of 12 inches. Holker¹¹ has pointed out that though the concentration of NaCl in the W.R. is limited to 0.85 per cent. there is no such limit in determining the optimum conditions or the interaction of serum and antigen alone. Consequently various concentrations of NaCl and of other electrolytes were tried. It was found, however, that in the higher concentrations (from 5 to 10 per cent. NaCl) spontaneous flocculation occurred more or less rapidly. Concentrations of 1 to 5 per cent. gave fairly stable antigens, but the results with positive sera were no better than with ordinary saline (0.85 per cent. NaCl). Further experiments in this direction will be conducted. An antigen diluted in 5 with saline is stable and keeps its sensitiveness unimpaired at least for several days.

other test entirely correct. The evidence on which such analysis rests is too lengthy to be published in extenso, and it is admittedly incomplete, but is given without known bias.

Group A, 4 cases, strong positive W.R., weak S.G. So far as can be judged from previous W.R.'s, and from clinical notes supplied, the W.R. more correctly reflects the condition in all four cases.

Group B, 4 cases, all moderate positive W.R.'s, two showing precipitation at 1/10, and two at 1/5. These are all old treated cases, in which the W.R. may be more correct in two, and the S.G. in two.

Group C, one case incompletely fixing 3 M.H.D. (± — —), and showing precipitation at 1/40 dilution. The S.G. is more probably correct, since the case gave three previous strong positive W.R.'s, the last three months earlier.

Group D, 3 cases, in all of which the S.G. is more likely to be correct, two having given three previous strong positive W.R.'s, and the other being on old untreated case.

Group E, 53 cases. In this group it is difficult and often impossible to decide from the clinical and other evidence which test is the more correct, and it is just this class of case which particularly needs controlling. It is impossible to give an extended analysis of these cases, but on the whole I judge the W.R. to be more correct in 15 cases, and the S.G. in 38. Of the 38 cases in which the S.G. is judged to be correctly negative 20 are almost certainly not syphilis; these include four control cases of other diseases, to which further reference will be made.

Group F, 2 cases, both giving negative W.R.'s, and both showing precipitation at 1/20 dilution. Both were cases of known syphilis, one a recently treated case, the other an old well-treated case, which gave a strong positive W.R. (fixation of 16 M.H.D.) three months earlier. In both cases the S.G. is judged to be the more correct.

Group G, 38 cases. Four of these were probably not syphilis. The remaining 34 were all treated cases, and both tests may be considered correct, the difference being comparatively small—e.g., W.R. $\pm -$, S.G. 1/2 or 1/5.

Among the total cases are included 23 parallel tests on 22 patients suffering from other diseases, mostly scarlet fever, diphtheria, and nephritis, in none of whom was syphilis suspected. Of these both tests were negative in 17 cases. Four gave negative S.G. reactions and $\pm -$ W.R.'s, which must be considered non-specific. The remaining case, which was tested twice, was a case of diphtheria, which on the twentieth day of the disease gave W.R. $\pm -$ and S.G. precipitation at 1/10 dilution; tested again five weeks later during convalescence the results were W.R. $\pm -$, S.G. nil. There were no signs or family history of syphilis, and the weak positives of both first tests remain unexplained.

Summarising the analysis I conclude as follows:—

	Correct.	Incorrect.
W.R. ...	454 = 90.8%	46 = 9.2%
Slide S.G. ...	475 = 95.0%	25 = 5.0%

During the period covered by these tests there was an opportunity of retesting the sera of 47 cases. The results, which are of some interest, are shown in Table III., and are arranged in groups as the second W.R. remained stationary, rose, or fell.

A FURTHER STUDY OF A PRECIPITATION TEST FOR SYPHILIS.

By C. Y. WANG, M.D., M.R.C.P. EDIN.,
B.Sc. MANCH.,

PROFESSOR OF PATHOLOGY, UNIVERSITY OF HONG-KONG
AND

R. A. BASTO, M.B., B.S. HONG-KONG,
LATE HOUSE SURGEON, GOVERNMENT CIVIL HOSPITAL,
HONG-KONG.

IN a previous paper published¹ by one of us (C. Y. W.), the results of the precipitation test for syphilis on 200 serums were recorded. We have now applied the test to the serums of 200 further cases, using here, as before, the Wassermann reaction (W.R.) as control. Without exception, the results of the test were read before the controls were known or the clinical notes of the cases consulted. Any preconceived idea as to the nature of the cases or the development of the W.R. controls which might have prejudiced the results can therefore be ruled out. Excepting for one or two modifications, the technique

followed here is precisely the same as that introduced in the previous investigation already published. Briefly stated, it is as follows.

Technique.

Antigen.—One part by volume of an alcoholic extract of heart (human heart 1 part, alcohol 3 parts; contact for three days at room temperature) is floated on 9 parts of saline in a tube kept at upright position. At the end of a quarter of an hour the tube, held at a slanting angle, is slowly rotated, the rotation to be continued for a quarter of an hour. The aim of the procedure is to obtain a *maximum turbidity of the fluid within the time stated*. As the result of further investigation we find that this diluted antigen should be used fresh, or within 24 hours, otherwise it tends to lose its efficiency. The undiluted alcoholic extract keeps well for many months, and in our experience for at least a year.

Tested Serum.—This is heated on the day of the test for 20 minutes at 55° C. in a water-bath. If the amount of serum available is small (say 1 or 2 drops) it should be diluted previous to inactivation.

Procedure of Test.—One tube, instead of two, is now used for each serum. To the tube, with a Wright's pipette, measure 5 drops of saline and 1 drop of the heated serum. If this had already been diluted to the required strength (1 in 6) before heating no saline is here added. Using the same pipette, place 6 drops of the prepared antigen. This gives a final dilution of about 1 in 10, allowance being made for the smaller volume of the antigen as delivered in drops. The tube is shaken and incubated at 37° C. overnight.

Interpretation of Results.—When the reading is taken the tube should be gently shaken up several times. A *positive* serum is signified by a distinct precipitation in the tube, with or without complete clearing of the fluid. The precipitate is fine and granular, and visible to the unaided eye. A *negative* serum is denoted by absence of precipitation, a few flakes floating in the fluid being disregarded.

Results.

A summarised result of the 200 specimens is given in Table I.

TABLE I.

	Total.	W.R. +	Pp.T. +
Clinically syphilitic—			
Primary (chancres)	16	12	16
Secondary	45	44	45
Tertiary	16	7	9
Treated	15	6	9
Clinically non-syphilitic	108	5	5
Total	200	74	84

For the W.R. control a deviation of three or more doses of complement over that of the control tubes was accepted as indicating a positive reaction. It will be observed that there are ten disagreements in the series, in all of which the reaction was positive with the precipitation test (Pp.T.) and negative with the W.R. The clinical history of these cases shows that four were chancres of five, three, two, and two weeks'

TABLE II.

	W.R. + Pp.T. +	W.R. - Pp.T. -	W.R. - Pp.T. +	W.R. + Pp.T. -
Total (First series ..	76	119	4	1
400 (Second series ..	74	116	10	0
	150	235	14	1
	96 per cent.		4 per cent.	

standing respectively, one was condyloma in a congenital syphilitic child, one general paralysis of the insane, one locomotor ataxia, and three were treated cases. In order to furnish sufficient data to justify an opinion on the merit of the test we have combined the results of the first and this (second) series of investigations in Table II.

¹ THE LANCET, 1922, i., 274.

The discrepancy between the two methods in the combined series therefore happened in 15 out of the 400 cases examined (4 per cent.). Ten of these 15 discrepancies have already been referred to and explained above. The remaining 5 belonging to the first series consist of 3 syphilitic and treated cases and 2 without clinical history.

Conclusions.

1. The test has been practised on the serums from 400 cases, and was controlled throughout by the W.R. An agreement with the W.R. was found in 96 per cent. of the serums.

2. Disagreements were shown in 15 specimens (4 per cent.), which comprise 13 clinically syphilitic cases and 2 unknown cases. Of the former, in every instance the reaction was positive with the precipitation test, but negative with the W.R. The latter consist of one positive and one negative W.R.

3. The findings would warrant the conclusion that the precipitation test as formulated above is as accurate as, and, in some cases of early and late syphilitic manifestations, even more so than the W.R. Further, the test is simple in application and involves the use of a minimum amount of serum, such as can readily be obtained from the finger.

We wish to record our indebtedness to Dr. Yeoh for providing us with some of the serums.

A CASE OF CHLOROMA.

By HUGH T. ASHBY, M.D. CAMB.,
M.R.C.P. LOND.,

VISITING PHYSICIAN TO THE MANCHESTER CHILDREN'S HOSPITAL;
AND

A. SELLERS, M.D. EDIN.,

PATHOLOGIST TO THE MANCHESTER CHILDREN'S HOSPITAL.

The following rare case of chloroma occurred in a boy aged 7 years, who was admitted to the Manchester Children's Hospital on Sept. 22nd, 1922, with the history that his eyes had been getting prominent for about a month. The previous history was good and he was a well-grown boy. There was a family history of tuberculosis.

Condition on Examination.—On admission to hospital there was a marked prominence of both eyes and a swelling about the size of a large plum over each temporal fossa. The boy appeared quite comfortable with the exception of headaches at times. There was no vomiting and his sight was good. The heart, lungs, abdomen, and urine were normal. The skin showed some bronzing for which we could not account. The exophthalmos was equal on both sides and so marked that a large amount of conjunctiva could be seen over the iris. There was no inflammation in either eye, though the eyelids could be closed only with difficulty. The tumour growth in each temporal fossa was hard and gradually lopped away to the surrounding parts. The patient was very prostrate and pallid.

Blood Examination.—The clinical laboratory report on the state of the blood on the 25th was as follows: Red corpuscles, 992,000 per c.mm.; white corpuscles, 5100 per c.mm.; haemoglobin, 50 per cent. The red cells stained faintly but were fairly normal as regards form and size. No nucleated or other abnormal forms were seen. A differential count of the leucocytes gave the following results: Polymorphonuclear cells, 27 per cent.; lymphocytes, 67 per cent.; large mononuclear cells, 5 per cent.; eosinophil cells, 1 per cent. No abnormal leucocytes were found.

Course of Case.—After admission to hospital all the symptoms became gradually worse, the eyes more prominent, the tumour masses larger, and he died two weeks later, on Oct. 7th, after an illness which lasted only six weeks. A week before death the eyeballs became greenish and inflamed, and the lids could not be closed. Headache was a prominent feature towards the end. The temperature on admission was 100° F., and rose to 105° on the day before death.

Post Mortem.—The body weighed 39 lb. There was some brownish-yellow diffuse pigmentation of the skin of the trunk, lower third of the abdomen, and inner side of the thighs. The external characters of the tumour are shown in the photograph. No other growths, enlarged glands, or bone

lesions were found. The tonsils were not enlarged. Heart normal, weight 115 g. Lungs, weight 230 and 210 g. There were some petechial hæmorrhages in the pleura covering the apex of the right lung, and both lungs contained scattered hard nodules about the size of a pea. The bronchial glands were enlarged and pigmented. There was a partly calcified caseous gland the size of a cherry-stone at the bifurcation of the trachea, and a completely caseous gland at the root of the right lung. Both lungs showed extensive bronchopneumonic patches. Stomach and intestines normal; no enlarged mesenteric glands or other tuberculous lesions. Liver, weight 730 g.; it was rather pale and contained some minute white rounded nodules. Spleen, weight 87 g.; rather soft and dark. Adrenals: The left adrenal contained a caseating tuberculous focus about the size of a pea.

The tumour on each side was situated beneath the temporal muscle, growing from the fascia on its under surface and infiltrating the muscle. It extended beneath the zygoma, into the orbits and over the superior maxilla. The bony structures were not invaded. The growths in the orbits surrounded and compressed the eyeballs, but these were not invaded. The lacrimal glands were both infiltrated with

Patient's appearance on admission to hospital.

new growth. The tumour was firm in consistence, softer in the orbit than elsewhere. It had a peculiar greenish-yellow colour and exuded much greenish serum on section. The colour faded on exposure to air and became more yellowish. It was recognisable after 24 hours, and was not revived by peroxide of hydrogen. The formalin in which some portions of tumour had been kept retained a yellow colour tinged greenish for some weeks.

Skull and brain normal; there were no intracranial growths. Thymus and thyroid normal.

Microscopical Findings.—Material was hardened in formalin and sectioned by freezing in gum. The stains used were hæmatestin-rubin and other simple stains, including those of Leishman and Giemsa. Sections from various parts of the tumour were tested with α -naphthol and dimethylparaphenylenediamine.

The tumour had the structure of a round-celled sarcoma. The cells were rounded or polygonal with a clear fairly abundant protoplasm and rounded nuclei. They were closely packed, with very little intercellular matrix, and often arranged in columns. Blood-vessels were very scanty and the amount of supporting connective-tissue stroma was small. The cells did not contain granules staining by Leishman, Giemsa, or eosin, and showed no evidence of the presence of ferments giving the indo-phenol reaction. The nodules in the lung, liver, and adrenal were tuberculous. No secondary growths were found in any of the organs and there was no diffuse leucocytic infiltration. The changes in the spleen require further investigation, but the chief condition found was an increase in the amount of pulp tissue and evidence of active hæmolysis. The red bone marrow showed no conspicuous change, but only the sternum could be examined.

The case resembles previously reported cases of chloroma but differs in some respects. The colour of the growth was not absolutely characteristic. Apart from the changes in the spleen, it affords no evidence in favour of the view that chloroma is allied to the leukæmias. Possibly the association of tuberculosis of the lungs and bronchial glands followed by a miliary tuberculosis modified the progress of the disease and the changes in the organs.

THE FATALITY OF PUERPERAL FEVER.

By REGINALD DUDFIELD, O.B.E.,

M.B. CAMB.,

MEDICAL OFFICER OF HEALTH, METROPOLITAN
BOROUGH OF PADDINGTON.

WHILE examining the rates of fatality of child-bearing over a long series of years a doubt has arisen as to the value of the fatality of puerperal fever when calculated on the number of cases notified (as published in the annual returns of notifications) and the numbers of deaths (as given in the annual reports of the Registrar-General). This memorandum has been written in the hope that someone more versed in statistical methods may be induced to express an opinion on the question.

From the latest report of the Registrar-General, that for 1921, it appears that 2211 cases of puerperal fever were notified in England and Wales during that year and that 1171 deaths were assigned to "puerperal sepsis"—Rubric 146 of the International Code. Those figures yield a fatality rate of 52.9 per cent. As soon as any examination is made of the rates obtained in the subdivisions of the country, it is seen that the rate just quoted cannot be accepted at its face value. In Table I. the subdivisions used by the Registrar-General have been followed.

TABLE I.—*Puerperal Fever, 1921.*

	Notified cases.	Deaths.	Fatality per cent.	Notified cases.	Deaths.	Fatality per cent.
England	2094	1060	50.6			
Wales	117	111	94.9			
London	353	142	40.2			
<i>England, excluding London.</i>						
<i>Wales.</i>						
Aggregates of—						
County boroughs	968	440	45.4	19	18	94.7
Administrative counties ..	773	478	60.6	92	93	94.9
Urban districts	534	303	56.7	67	59	88.0
Rural districts	239	175	73.2	31	34	110.0

Variation of Fatality Rate.

A fatality rate varying in one year from 40.2 to 110 per cent. invites inquiry as to the causes of such variation and offer for solution a problem as to the true value of the rate. The hypothetical rate (110 per cent.) observed in the aggregate of rural districts in Wales hints at one explanation of the wide variation—viz., incomplete notification.

It appears to be reasonable to assume that notification will be more complete within the County of London than in any other part of the country. For the whole country the rate in 1921 was 40.2 per cent., but on examining the rates in the five groups of cities and boroughs which are included within the county, the rate varies from 28.5 (Central) to 48.6 (North) as shown in Table II. In other words, the variation ranges from 29 per cent. below to 21 per cent. above the rate for the county.

TABLE II.—*Puerperal Fever in London, 1921.*

	Notified cases.	Deaths.	Fatality per cent.	Index numbers.
West	78	24	30.8	766
North	72	35	48.6	1206
Central	7	2	28.5	709
East	59	20	33.9	818
South	137	61	44.5	1007
London	353	142	40.2	1000

On taking out the rates for the individual cities and boroughs, still greater variations are found. As regards London, in the West districts the maximum rate was 62.5 (Kensington) and the minimum 14.2 (Chelsea)—a range of from 103 per cent. above to 54 per cent. below the rate for the group. In the North the maximum was 100 per cent. (Hampstead)

and the minimum zero (Stoke Newington)—a range of from 106 per cent. above to 100 below the rate for the group. In the Central, the maximum was 100 (Holborn) and the minimum zero (City of London)—a range of from 251 per cent. above to 100 below the rate for the group. In the East, the maximum was 38.0 (Stepney) and the minimum 20.0 (Bethnal Green)—a range of from 12 per cent. above to 41 below the rate for the group. In the South, the maximum was 78.5 (Camberwell) and the minimum 22.2 (Lewisham)—a range of from 31 per cent. above to 50 below the rate for the group.

Setting aside the districts in which no death from puerperal sepsis was recorded during the year, the fatality, as obtained from the recorded numbers of notified cases and deaths, shows an amplitude of variation from 100 per cent. to 14.2—that amplitude occurring in an area in which it has been assumed that notification is most complete.

Outside the County of London there are 82 county boroughs (78 in England and 4 in Wales) and 61 (each) aggregates (or groups) of urban and rural districts (48 in England and 13 in Wales). Of the 204 areas, or groups of areas, 93 present special features.

In 10—2 C.B. (England), 6 A.U.D. (England, 2; Wales, 4), 2 A.R.D. (England)—there were 16 deaths and no notified cases.
In 23—11 C.B. (England, 10; Wales, 1), 3 A.U.D. (England, 2; Wales, 1), 14 A.R.D. (England, 11; Wales, 3)—the (114) deaths exceeded the (63) notifications.
In 28—13 C.B. (England, 11; Wales, 2), 5 A.U.D. (England), 10 A.R.D. (England, 6; Wales, 4)—the (180) deaths equalled the (180) notifications.
In 27—3 C.B. (England), 14 A.U.D. (England, 11; Wales, 3), 10 A.R.D. (England, 7; Wales, 3)—there were no deaths and no notifications.
C.B., County boroughs. A.U.D., Aggregate urban districts. A.R.D., Aggregate rural districts.

After elimination of the areas, and groups of areas, in the first two of the above four categories, the rates set out in Table III. are obtained.

TABLE III.

Aggregates of—	England, excluding London.			Wales.		
	Notified cases.	Deaths.	Fatality per cent.	Notified cases.	Deaths.	Fatality per cent.
County boroughs	944	396	41.9	18	15	83.3
Administrative counties ..	743	417	56.1	90	71	78.8
Urban districts	530	295	55.6	65	51	78.4
Rural districts	213	122	57.2	25	20	80.0
Totals	1687	813	48.1	108	86	79.6
England and Wales: fatality, 47.4%.						

In 66 county boroughs, 35 aggregates of urban districts and 38 of rural, the deaths assigned by the Registrar-General to puerperal sepsis were, in each area or group of areas, *not in excess* of the notified cases of puerperal fever. The observed fatalities in the boroughs and aggregates have been tabulated at 10 per cent. intervals. (Table IV.)

TABLE IV.—*Puerperal Fever, 1921.*
England and Wales, excluding London.

Fatality rate per cent.	County boroughs.	Aggregates of—		All areas.
		Urban districts.	Rural districts.	
10—	4	—	2	6
20—	4 (1)	3	1	8 (1)
30—	9	2 (1)	4	15 (1)
40—	10	3	—	13
50—	11	9 (2)	9 (2)	29 (4)
60—	8	7	3 (1)	18 (1)
70—	6	4	5	15
80—	1	4 (1)	1	6 (1)
90—	—	1 (1)	—	1 (1)
100—	13 (2)	5	10 (4)	28 (6)

The figures in parentheses are those for Wales and are included in the figures preceding them.

Regarding Table IV. as an ordinary frequency distribution, the following means have been obtained:

	Per cent.
County boroughs.. ..	52.5
Aggregates of urban districts ..	60.5
Aggregates of rural districts ..	53.2
England and Wales	58.5
England	57.4
Wales	72.0

It appears to be almost hopeless to arrive at a conclusion as to the true fatality rate from the foregoing calculations. All that can be written is that the rates obtained raise suspicions that the notification of puerperal fever is very incomplete, and that in assigning deaths to puerperal sepsis the Registrar-General follows a rule differing from that adopted by the profession in diagnosing the disease. It has long been recognised that a definition of "puerperal fever" is wanted for the purposes of notification.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF LARYNGOLOGY: SUMMER MEETING.

THE summer meeting was held at the Manchester Royal Infirmary on June 15th and 16th, with Mr. C. A. PARKER, the President, in the chair.

The first part of the programme was devoted to the reading and discussion of papers.

Mr. DOUGLAS GUTHRIE (Edinburgh) read a paper on

Chronic Hyperplasia of the Upper Jaw.

He said that this disease, although rare, might furnish a clue to the solution of some of the problems of bone pathology. The microscopic appearance closely resembled otosclerosis, although the two diseases perhaps differed widely in their pathogenesis. Mr. Guthrie described two cases, of a boy aged 5 and of a girl aged 16, in both of whom the bony enlargement of the maxilla was unaccompanied by pain or other symptoms. Lantern slides were shown to illustrate three specimens from the Museum of the Royal College of Surgeons of England, including an upper jaw excised by Lord Lister. The relationship of the disease to leontiasis ossea, to unilateral hypertrophy, and to other osseous tumours was also discussed and illustrated.

Mr. T. B. LAYTON (London) said there were many types of this disease, some of which were typical examples of leontiasis ossea. It was essential to separate the types, but he considered that some microbic toxin was responsible and reminded the section that a similar disease occurred in the anthropoid ape and in the chimpanzee.

Mr. F. H. WESTMACOTT (Manchester), referring to his work on this subject, pointed out that the bony swelling involved the canine fossa and originated from the alveolus. The bony changes were always limited by the orbital plate, and a diminutive antrum of Highmore was present. He regarded the condition as a reversion to an embryonic type, a reconstruction of the bone, and in no way associated with infection.

Mr. J. ARNOLD JONES (Manchester), from a series of 53 cases, offered some

Clinical Observations on the Lingual Tonsil.

He divided the symptoms into three groups: (1) Vague aches, pains in the throat; (2) paroxysmal cough, and (3) dysphagia. The appearance of the lingual tonsil varied from a granular or varicose condition to definite gross hypertrophy. Discussing treatment, Mr. Jones referred to the dangers of removal of hypertrophies with the guillotine, and preferred painting the tonsil two or three times a week with a solution of 1 in 40 silver nitrate, or making linear cauterisations with the electric cautery. As to the results of treatment, out of 41 replies 11 reported

cures, 11 great improvement, 15 improvement, and 4 no improvement.

The PRESIDENT and several members took part in the discussion, and it was generally considered that in the majority of cases the importance of the lingual tonsil in the production of symptoms was overestimated.—Mr. JONES, however, maintained that the lingual tonsil was often overlooked, and that the treatment which he had outlined, simple as it was, was worthy of a more extended trial.

Dr. D. R. PATERSON (Cardiff) discussed the

Treatment of Large Foreign Bodies Impacted in the Gullet.

He pointed out that in the majority of cases such bodies were impacted in the cervical portion of the gullet. The difficulty of extraction per vias naturales was frequently enhanced by the septic nature of the foreign body, its jagged or pointed contour, and the length of time it had been present in the gullet. He insisted on the importance of a careful and studied survey of the case before adopting endo-oesophageal treatment. Reference was made to the extreme rapidity with which some foreign bodies induced ulceration of the oesophageal wall, the presence of a foetid odour or pyrexia being an indication for extreme caution during extraction. Any perforation, actual or suspected, of the oesophageal wall was an indication for an external oesophagotomy. Dr. Paterson invited opinions as to whether it was not sounder treatment to resort to the external operation in cases of difficult endo-oesophageal extractions or presence of sepsis, without actual perforation of the gullet wall.

Sir WILLIAM MILLIGAN advocated the use of the expanding oesophageal tube, and was of the opinion that an external operation should be performed if the point of the foreign body was deeply embedded in the oesophageal wall and difficult to extract.

Dr. WILLIAM HILL regarded foreign bodies with hooks or teeth impacted in the pharynx as an indication for the external operation.

Mr. MUSGRAVE WOODMAN (Birmingham) communicated a further study of the varieties of

Malignant Disease of the Nasal Accessory Sinuses.

with lantern demonstrations of microphotographs. He pointed out the necessity for acquaintance with the histology of the normal ethmoid, and considered that several sections of a tumour had to be made before a definite opinion as to its nature could be evolved. In conclusion he illustrated, by lantern demonstration, some further suggestions for the surgical treatment of this condition.

Mr. F. H. DIGGLE (Manchester) read a paper on Diseases of the Thyroid Gland in their Relation to Laryngology.

He discussed the incidence of laryngeal and tracheal complications in benign diseases of the thyroid gland, with special reference to vocal cord paralysis and tracheal compression. He stated that of 34 cases examined during the last 18 months 7 presented such complications. He considered, however, that this proportion was probably too high. Of the 34 cases examined 20 were simple parenchymatous goitres, 6 adeno-parenchymatous, 6 exophthalmic, and 2 cystic goitres. He had only seen two cases of vocal cord paralysis in the cases examined, one a functional adductor paresis in a case of exophthalmic goitre and the other a right abductor paralysis due to hæmorrhage into a cystic goitre. After referring to the incidence of laryngeal paralysis in retro-oesophageal or retro-sternal thyroid extensions, he pointed out that tracheal compression or distortion was a more frequent complication. Radiographs were shown of two cases, aged 17 and 15 years respectively, illustrating bilateral tracheal compression and the relief of such after partial thyroidectomy.

Mr. H. TILLEY referred to a recent case in which an extension of the thyroid gland had insinuated itself between the thyroid ala and the lateral laryngeal wall, producing a bulging inwards of one-half of the larynx.

At noon on June 16th more papers were read.

Mr. D. L. SEWELL (Manchester), in a paper on the *After-treatment of Empyema of the Maxillary Antrum (Denker's Operation)*,

discussed the relative advantages of Denker's operation. He preferred to fashion a nasal flap, and to turn it on the floor of the sinus, packing it down with a narrow strip of bismuth gauze. He left the buccal wound unsutured, and on the fourth day removed the gauze through the buccal opening. Concerning subsequent irrigation of the sinuses, Mr. Sewell was of the opinion that the best results were obtained if no such treatment was adopted and only simple gentle nasal douching employed on and after the seventh day. For cases with persistent discharge in spite of such treatment he discussed the advantages of irrigation with silver nitrate and colloidal silver preparations. He was of the opinion that too zealous treatment by irrigation frequently spoilt an operative result.

Mr. J. F. O'MALLEY traced the *Evolutionary Changes which the Nose Undergoes in the Vertebrata*.

Beginning with the lamprey and continuing through fishes, amphibia, reptiles, birds, and mammals to man, he traced the stages of the evolution of the nose with its accessory sinuses as present in man. Running parallel with the anatomical variations he demonstrated the physiological adaptations to origin, passing through the phases of a pure olfactory organ, then with powers related to assimilation and taste, and finally to that of a respiratory organ at first subsidiary to smell and then of equal importance.

Exhibitions of Cases and Demonstrations.

The afternoon of June 15th was devoted to the examination and discussion of several interesting clinical cases. The local members of the section, together with Mr. WOODMAN and Dr. DAVID THOMSON (Blackpool), had collected together a full and complete variety of cases which gave rise to instructive and useful discussion.

On the morning of June 16th Dr. P. WATSON-WILLIAMS (Bristol) demonstrated his technique and method of exploration of the nasal accessory sinuses.

Dr. IRWIN MOORE (London) demonstrated his method for the reduction or destruction of the hypertrophied or diseased tonsil by means of caustic soda and slaked lime (London paste).

An interesting demonstration of radiographs illustrating pharyngeal pouches, cardiospasm, and other lesions associated with the specialty were shown by Dr. MORRISON and his colleagues in the new X ray department of the Royal Infirmary.

Dr. A. BURROWS showed cases treated by radium, and demonstrated his methods of application in malignant diseases of the nose, pharynx, and larynx.

The annual dinner of the section was held at the Clarendon Club on June 15th, and the dinner, as well as the other meetings of the section, were voted most successful functions.

SECTION OF OPHTHALMOLOGY.

A MEETING of this section was held on June 8th, under the presidency of Mr. A. L. WHITEHEAD, when a number of cases were shown.

Macular Change with Tremor.

Mr. H. M. JOSEPH showed a case of progressive macular changes associated with tremor. The patient was a woman aged 34. Two and a half years ago she had tremor of the right hand, but no visual defect. When he saw her for the first time two years ago there were light spots about both maculae, and the corrected vision was 6/12. Since that date the spots had greatly increased in number. Vision had now fallen to 6/18, and the tremor was more marked and extensive. Wassermann was negative.

Mr. RAYNER D. BATTEN regarded the case as an adult instance of cerebro-macular disease. Probably the same toxin might be at work, producing different symptoms at different age periods. Infantile, juvenile,

and senile types were now recognised, and the present case seemed to supply the missing link, the adult type. He entered into the reasons he held that view, and showed slides of various cases he knew of. —Mr. F. A. JULER referred to a case under Mr. Leslie Paton, a boy, aged 18, which Mr. Paton diagnosed as cerebro-macular degeneration, and said he (Mr. Paton) regarded it as a connecting link between amaurotic family idiocy and later cases of cerebro-macular degeneration. —Dr. GORDON HOLMES said he was familiar with this tremor since the epidemics of lethargic encephalitis. He did not suggest that this patient's condition was a sequel to lethargic encephalitis, but he thought the area of brain affected agreed in the two conditions. The most important pathological lesion in these cases was disease in the substantia nigra and in the neighbourhood of the mesencephalic nuclei; it seemed to be a primary degeneration of certain portions of the grey matter of the brain. —The PRESIDENT said that in the cases of encephalitis lethargica he saw he had not noted any fundus changes, a curious fact if the basal ganglia were affected.

Familial Nodular and Reticular Keratitis.

Mr. MONTAGUE HINE read a paper on this subject, based on three cases shown. This family, he said, helped to demonstrate a close connexion between the two conditions which did not appear so obvious when seeing individual cases. Mr. Basil Graves, who examined these three cases with the corneal microscope, aptly described the appearance seen in the two younger patients as a "fine sheeny speckling," and suggested that the tissue might be impregnated with a fine translucent granular deposit, which might have a refractive index different from that of the cornea. The girl, aged 10, gave a history of slight headache, but no intolerance of light. Right vision was 6/12, left 6/9. In her the opacity consisted of a number of fine lines, many of which were seen to be composed of tiny dots; but the lines here did not form a meshwork, but remained separated and uncrossed. One line suggested an obliterated vessel, resulting from previous inflammation. In the left cornea there was a combination of two of the linear opacities with several of the small rings, similar to those in her brother. The mother, aged 36, said that her eyes had worried her since infancy; she had not had them examined before February last, when she came to be tested for glasses. Right vision was 6/18, left 6/12. The central area of the cornea was seen to be studded with numerous, rather closely-set greyish-white opacities, some in the form of rings, others nodular, while in places the nodules became confluent. The periphery of the cornea was clear in each eye. The boy, aged 14, gave a history of severe headaches and intolerance of light since infancy. His cornea showed very similar changes to those seen in his mother. There was one child whose eyes were normal. In all the cases the Wassermann was negative, but the maternal grandfather was said to have had syphilis.

Mr. H. NEAME spoke of a case under Mr. J. H. Fisher's care who had lines of opacity in one eye, and nodules in the other; the lines appeared to be at about the middle of the substantia propria.

Tuberculous Conjunctivitis.

Mr. R. L. REA showed a young woman, aged 23, with tuberculous conjunctivitis, in the form of ulcerative patches on the lids of both eyes. He had arranged for her to be sent to Leysin, in Switzerland, to have the direct sunlight treatment, from which he had seen there very good results. He hoped to show her again after she had received that treatment.

The Embryology of Congenital Crescents.

Miss IDA C. MANN read a paper on some suggestions on the embryology of congenital crescents, which was supplemented by some excellent micro-photographs and drawings shown by the epidiascope. The main thesis is as follows: The group of cases under consideration are characterised by the fact that they

are congenital, stationary, not necessarily associated with any one error of refraction, and situated, in 70 per cent. of the cases, below the disc. There is, apparently, some factor which determines the greater proportion of inferior crescents, which must be sought in the normal development of the disc, since an abnormality is more likely to be associated with a normally existing embryonic structure than it is to arise *de novo* as a pure aberrance. The embryonic structure in this case is the choroidal fissure. The presence of congenital crescents in other situations does not detract from the fact that the choroidal fissure is the determining factor in the inferior type. The presence of the fissure will merely account for the preponderance of this type, since the essential condition for the formation of a crescent is that the pigmented outer layer of the optic cup should not reach quite up to the insertion of the optic stalk. The presence of the fissure merely allows of this occurring more easily below the disc than elsewhere. From the illustrations shown it can be seen that the essential difference from the normal consists of the failure of the pigment epithelium and nuclear layers of the retina to reach the edge of the optic disc in its lower part; hence there is a small area below the disc in which all the elements of the retina except the nerve fibre layer are absent, so that this layer is separated from the sclerotic only by a very thin extension of the choroid. Developmentally it has been shown that eversion of the unpigmented layer of the optic cup normally takes place in the upper end of the choroidal fissure. This is seen in a large number of vertebrates. In some animals, including man, the small everted portion of the inner layer loses its connexion with the rest of the inner layer and disappears, but in some other types (birds) the connexion is retained and nerve fibres grow into the everted projection. If in man the everted portion developed aberrantly and retained its connexion with the inner layer, a condition resembling that normally present in birds might result. Such a condition is present in a congenital inferior crescent, which bears a striking resemblance to the structure of the lower part of the disc of the normal bird. It may be said that congenital crescents in any situation are due to the failure of the pigment epithelium to reach the site of implantation of the optic stalk. This failure may occur anywhere, since aberrant differentiation of the various parts of the secondary optic vesicle is known to occur. It is, however, much more likely to occur below the disc than elsewhere, since it is normal here at one stage of development in man. Hence the greater frequency of inferior crescents, which can be looked on as developmentally homologous with the cauda of birds, the architectural basis of the cauda being present, though small, in the normal human embryo. The failure of the choroid is directly correlated with the absence of the pigmented epithelium, and the occasional failure of the sclera has its parallel in the retardation of condensation along the fissure during development.

The PRESIDENT complimented Miss Mann on her exposition and the beauty of her slides.—Sir WILLIAM LISTER argued that the inferior crescent was a retraction crescent, similar to the ordinary retraction crescent of myopia occurring on the macular side.—Sir JOHN PARSONS agreed with Miss Mann's view. In many cases the condition was associated with failure in closure of the choroidal fissure. With regard to the myopic so-called retraction crescent—a term he did not like—he thought this was probably an atypical coloboma, and that it had no relation to the stretching of the walls of the globe associated with myopia.

Miss MANN replied that the presence of staphyloma below the disc could also be explained as part of the retardation of the sclerotic condensation along the lines of the fissure. She agreed that myopic crescents also had a congenital explanation, though in them some pathological process was superimposed.

Mr. P. DOYNE read a brief paper on the Tournay reaction, and it was discussed by Mr. J. H. FISHER and Mr. RAYNER BATTEN.

NORWICH MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL meeting of this Society was held at the Norfolk and Norwich Hospital on June 5th, with Dr. ARTHUR CROOK, the President, in the chair.

Insulin in Diabetes.

Dr. H. J. STARLING brought forward two cases of diabetes to illustrate the benefits and limitations of insulin. Case 1 was a girl of 18 who was first admitted to hospital in October, 1919, with a long previous history of thirst and loss of weight. She had 32 gr. of sugar per oz. of urine with a total output in one day of 2030 gr. Starvation for five days made the urine sugar-free. This case for three and a half years had been kept on a very low carbohydrate diet, which she only varied occasionally when temptation overtook her. She had steadily increased in weight, had always been of a healthy colour, and had managed to establish her menstrual periods lately. Case 2 was a man, aged 30, admitted to hospital on April 16th, 1921, with high sugar excretion and marked acetonuria. Was kept in 12 months. Starvation for varying periods of 2-5 days made the urine sugar-free, but after 2-4 days of meat, eggs, and 10 oz. of 5 per cent. vegetables, sugar always reappeared, and his weight kept stationary. He was readmitted in June, 1922, in a condition bordering on coma; acetonuria and sugar excretion very high. As starvation did not result in abolition of sugar it was given up, and he was put on a diet containing 51 g. of carbohydrate and of 1435 calories per day. His daily output of sugar for the past six months averaged 784 gr. (46 g.) and he therefore retained a daily average of 77 gr. (5 g.) of carbohydrate. Insulin—10 units—was given on May 7th, and one slice of bread was given in addition to his normal diet, but the sugar excretion went up to 1560 gr. (93 g.). The daily amount of insulin was then increased, until for the past three days he had been having 10 units at 6 A.M., 20 units at 12, and 10 units at 6 P.M. = 40 units a day. For the past 48 hours he had been sugar-free, except for the specimens tested at 6 A.M. and 8 A.M. That dose of insulin was therefore about correct to enable him to retain the present intake of carbohydrate. The blood-sugar before insulin was given was 0.56 per cent., afterwards only reduced to 0.52.

Dr. Starling considered that insulin was of immense value in diabetic coma, in which condition 80-100 units should be given with large doses of glucose, preferably intravenously. He stressed the importance of frequent estimations of the blood-sugar. If that was not done there was only one other factor by which the dose of insulin might be graded. In order to prevent an overdose being given it was necessary that a small amount of sugar should always be present in the urine, which necessitated the blood-sugar remaining permanently at a higher level than that which the pancreatic cells could deal with. That practice was diametrically opposed to Allen's treatment, which aimed at keeping the urine sugar-free, and thus giving the cells of the islands of Langerhans a chance of recovering their proper function. When the sugar excretion could be controlled by dieting, insulin was not required, but its use was essential in a class of cases in which sugar was always present in the urine in spite of the most careful dieting. The highest percentage of blood-sugar occurred between 6 A.M. and mid-day, and thus the larger doses of insulin should be given in the morning. It was, however, dangerous to give the insulin over-night, as someone had suggested, as with no meal to follow symptoms of an over-dose might come on during sleep and be far advanced before any signs of it were observed. At present insulin therapy was in its infancy and the drug should not be given indiscriminately, or by anyone not fully conversant with its effects.

Exhibition of Cases and Specimens.

Mr. E. W. EVERETT showed four cases and specimens, including a boy on whom he had operated

for lateral sinus thrombosis. On March 17th he had done a radical mastoid operation. On the 28th the patient had a rigor, after which rigors occurred every second, third, or fourth day. The patient also had headache and a septic temperature, but no vomiting. After a very severe rigor on April 13th the boy was operated on; the thrombosis, which did not extend into the jugular vein, was thoroughly cleaned out and packed; after the operator and his assistant had changed their coats and gloves the jugular vein was tied above the origin of the facial vein. The patient made a good recovery.—Sir H. BALLANCE congratulated Mr. Everett on the result of his operation. In his opinion better drainage was obtained in these cases by ligaturing the jugular vein below the origin of the facial, and leaving the upper end of the jugular open for drainage.

Mr. Everett's second case was that of a woman who had obstruction to labour at term by a right ovarian fibroid which was impacted behind the uterus. Cæsarean section was done, and the tumour removed with great difficulty. The third specimen was a colossal ovarian tumour blocking up the whole pelvis, in a woman about eight months' pregnant. She was operated on before labour commenced, and the whole tumour and uterus, together weighing 38 lb., removed by Cæsarean section. The child was extracted alive, but died in half an hour. The operation was followed by severe secondary hæmorrhage. As no bleeding-point could be found she was treated by intravenous injection of gum—6 per cent.—and made a good recovery. Mr. Everett also showed a stone impacted at the vesical end of the ureter, removed by suprapubic cystotomy.

A Case of Blastomycosis.

Dr. F. SUGDEN showed a case of blastomycosis in a man, aged about 25, which had been modified by treatment. The eruption was on the neck and the left hand corner of the mouth, and it at first sight looked like impetigo contagiosa. He came to the conclusion, however, that it was a fungus growth, and that the infection was probably derived from horses. After two examinations at the laboratory, the diagnosis of blastomycosis was confirmed. Treatment had been removal by a sharp spoon of the papillomatous growth at the margin of the eruption, followed by starch poultices and later the application of a modification of Dakin's solution. There was considerable improvement, though not a permanent cure.

Dr. S. H. LONG showed a case of pseudo-hypertrophic paralysis in a boy of 8, who exhibited all the typical symptoms. Treatment by massage was of no avail in this case.

DALRYMPLE HOUSE, RICKMANSWORTH.—The report of Dr. F. S. D. Hogg, the superintendent of Dalrymple House, Rickmansworth (Homes for Inebriates Association), which deals with the year ending Jan. 31st, 1923, brief though it is, contains many points of interest to the medical profession. Owing, no doubt, to the financial and mental strain of the war, and the resulting sequelæ, there has been a notable increase in the number of patients who ascribe their alcohol habit to business and domestic worries, and some 33 per cent. of the inmates allege these as a primary cause. During the year 79 patients were admitted, nine of whom were drug addicts, and the remainder subjects of alcoholic excess. The private patients numbered 55 and those treated under the Inebriates Act 24. The ages of the patients ranged from 21 to 77, but Dr. Hogg points out that persons over 70 are rarely admitted as it is then found usually too late to hope for improvement. He states, however, that of three patients admitted during the past 21 years over that age, one continued to do well till the time of his death, and another, now aged 84, has not touched drink or drugs during the last 12 years. Very young patients also do not prove satisfactory, as they resent control and do not realise the need for any alteration in their habits. The average length of residence for treatment, taking the figures over a number of years, has been 20½ weeks, but in some cases a few days' residence has resulted in marked improvement, when discharge has followed. Recent years have seen an increased number of methylated spirit drinkers, and the suggestion is made that if methylated spirit were sold to the public "doctored" with tartar emetic the consumption of the liquid as a stimulant would be stopped.

Reviews and Notices of Books.

PRACTICAL MIDWIFERY.

By GIBBON FITZGIBBON, M.D., F.R.C.P.I., Master, Rotunda Hospital. London: J. and A. Churchill. 1923. With 175 illustrations. Pp. 534. 16s.

THE midwifery practice followed at the Rotunda Hospital is held in such high esteem that a text-book by the Master may well be regarded as authoritative. It is unnecessary to dwell on the sound teaching or to stress the particular respects in which the technique of the Dublin school differs from current practice in this country. Suffice it to say that the book is an excellent text-book, well planned and well stuffed with clear information. There are a few specially interesting ideas, notably in the section dealing with the difficult subject of retraction of the uterine muscle fibre. Dr. FitzGibbon considers that retraction follows from reduction in the intra-uterine tension, while contraction naturally follows uterine stimulation. Retraction therefore does not occur until contraction has produced an alteration in the intra-uterine tension sufficient to reduce it below the level required to maintain equilibrium. The author strongly recommends and describes clearly the many advantages of rectal examination during labour in preference to vaginal examinations. Schultze's method of detachment of the placenta is regarded as the normal and Matthews Duncan's is described as an abnormal method; the teaching that the former only occurs when the placenta is attached at or near the fundus of the uterus is not accorded any support. The statement that when the placenta is detached according to the mechanism outlined by Matthews Duncan the membranes are often torn and retained will hardly meet with acceptance on the part of most obstetricians. The need for a post-partum vaginal examination is stressed. The description of plugging the vagina is, as might be expected, very good; but it is perhaps unfortunate that the author should illustrate it being employed for central placenta prævia, since many authorities disapprove of its use for this condition. The account of the toxæmia of pregnancy is particularly clear; the author shows wisdom in making no attempt to include all the various theories of origin, for many of which there is in reality not much foundation.

The detailed description of the treatment adopted for eclampsia at the Rotunda Hospital will be read with much interest, since at the present time the non-operative treatment of this complication of labour is being widely advocated. It is instructive to see how strongly Cæsarean section, with its mortality of some 32 per cent., as a method of healing eclampsia is condemned. The Rotunda method, which includes gastric lavage, purgation, colon lavage, submammary infusion, poultices to the loins, and occasionally venesection or intravenous infusion has been carried out in some 214 cases with a total of 19 deaths, a death-rate of under 9 per cent. Under the heading of induction of premature labour, Dr. FitzGibbon describes the method of using a No. 20-24 soft rubber stomach-tube, which is pushed through the cervix and allowed to coil itself up below the presenting part, the whole of the tube being introduced into the lower uterine segment. The advantages claimed for this method are the ease with which it can be carried out, the certainty with which the tube can be sterilised by boiling, the minimum of manipulation, and the fact that the whole tube is contained within the uterus and nothing projects through the cervix into the vagina.

We have said enough to show that this book contains much of interest. The illustrations are good, there is a full index, and it may certainly be read by the student and practitioner as a safe guide to the best practice in midwifery.

DISEASES OF THE EAR.

A Practical Handbook for Students. By Sir WILLIAM MILLIGAN, M.D., Aurist and Laryngologist to the Royal Infirmary, Manchester; and WYATT WINGRAVE, M.D., Pathologist to the Central London Throat and Ear Hospital. London: William Heinemann. 1923. Pp. 191. 12s. 6d.

THIS handbook supplies sound instruction in a concise form on diseases of the ear, and may be read by the student as a reliable and authoritative introduction to otology. In compressing a large subject into the space of a small handbook, it is naturally difficult to decide what to omit, what to mention briefly, and what to describe at greater length. The authors do not appear to have solved the problem with entire success in this case; for, of the 178 pages of text, page 109 is reached before we have passed the external auditory meatus and arrive at diseases of the drum. Much of the detail about examination of the buccal cavity, pharynx, nose and naso-pharynx might well have been omitted; general practitioners have no occasion to use a palate retractor or the Weber-Liel tympanic tube. A number of pages are occupied by diseases of the auricle, many of which are very rare and of more interest to the dermatologist than to the otologist. By careful selection of matter more space could have been found for the all-important subject of otitis media in its various forms. Despite this lack of balance, the book has many merits. It is written in an interesting style, and the illustrations are plentiful and good; it should prove useful to the senior student, for whom it is intended, and we hope, with the authors, that it may stimulate a desire for increased information.

COLLOIDS.

Théorie et pratique des colloïdes en biologie et en médecine. By W. KOPACZEWSKI, Docteur en Médecine, Docteur ès-Sciences, Professeur à l'Institut des Hautes-Études de Belgique. Paris: Vigot Frères. 1923. Pp. 308. Fr. 25.

THIS excellent and original book from the pen of one who has devoted much labour and thought to the subject of colloid chemistry will be welcomed. It is up to date throughout and the practical portions comprise much not generally included in works on practical colloid chemistry; in fact, it deals in a clear, though brief, manner with all the ordinary technique of physical chemistry which is likely to be involved in investigations on colloids; such methods as electric conductivity, cryoscopy, and concentration cells are fully treated. The chapters dealing with electric transport, viscosity, surface tension, nephelometry, and ultramicroscopy will be found to contain methods not given elsewhere. The whole work, which is well illustrated and provided with an excellent bibliography, should fill the need which is felt in France for such a book, and will assuredly find its way into the libraries of all in this country who are interested in the application to medical problems of the findings of colloid chemistry, for they could not have a better guide.

Klinische Kolloidchemie. By Dr. ERNST JOËL. Berlin, Dresden, and Leipzig: Th. Steinkopff. 1923. Pp. 124. 2s. 2d.

A SERIES of nine lectures dealing with applications of physical, and especially colloid, chemistry to medical practice. Though academic in form, they provide interesting reading for those sufficiently familiar with the language and with the elements of physical chemistry; if we may judge from the contents of these lectures, the average German clinician is more given to theorize than the English practitioner. Theories of colloid swelling play a large part in some of the hypotheses which are advanced in these lectures. It is certainly interesting, even if we are not inclined to follow all the author's reasoning, to see how extensive may be the applications of colloid and physical chemistry.

TUBERCULOSIS.

Environment and Resistance in Tuberculosis. By ALLEN K. KRAUSE, Associate Professor in Medicine, Johns Hopkins University; Director, Dows Tuberculosis Research Fund; Lecturer, Trudeau School of Tuberculosis, &c. Baltimore: Williams and Wilkins Company. 1923. Pp. 137. \$1.60.

THE author, who is editor of the *American Review of Tuberculosis*, has compressed into two chapters much thought, and suggestions which provoke thought, on the subjects of environment and resistance in relation to tuberculosis. In the chapter on Environment doubts are cast on the general validity of the Andvord-Römer teaching that practically all the tuberculosis of adult life can be traced to auto-infection resulting from tuberculosis contracted in childhood. The author cannot help believing that the everyday life of man provides conditions that make for a not inconsiderable number of tuberculous re-infections from without, in which the time and quantity of re-infection may be so ordered as to cause a break-down. With regard to heredity, it is pointed out that nervous instability and over-irritability are certainly transmitted from one generation to another, and the suggestion is made that nervous irritability, which must regulate cellular activity in general, may ultimately be found to influence the origin and development of infections in a marked degree. In the chapter on Resistance the author ventures the opinion that allergy undoubtedly furnishes the key which bids fair to unlock the outstanding riddle of tuberculosis, "the mystery which so baffled early observers and so long delayed a more rational concept of the disease." The author pokes gentle fun at those who regard the most acute symptoms of tubercle as the products of mixed infection, and he considers the "mixed infection" view as really nothing more or better than the Virchowian doctrine that "the worst thing that can happen to a consumptive is that he becomes tuberculous." Whether he is enunciating truisms or propounding views perilously close to the heretical, the author puts his thoughts into words with commendable brevity and rare lucidity.

Lungentuberkulose. Second edition. By Dr. O. AMREIN. Berlin: Julius Springer. 1923. Pp. 141. 5s.

AN important function of a preface is to give the reader an inkling of the spirit in which the author has approached his task. The note which Dr. Amrein sounds in the preface to his book is one of modesty; he does not propose to startle his readers with new or unorthodox views, but to give them a summary of many years' first-hand clinical knowledge acquired in a sanatorium. The book is written for the practitioner in order to fill up gaps in his knowledge. But the book is also well worth reading by specialists—particularly by specialists who prefer new lamps to old and who, in running after the latest idea in tuberculosis treatment, are liable to forget the value of well-tried remedies. Take, for example, such a remedy as natural sunlight. It has lately become a fetish, and the success it has undoubtedly achieved in surgical tuberculosis has enticed the unwary and inexperienced into recommending it for pulmonary tuberculosis. Many ill-effects, including hæmoptysis, have followed sun-baths in phthisis, and this should be remembered. With regard to specific treatment and the choice of route by which to give tuberculin, the author is most impressed by Sahli's method of giving tuberculin by intracutaneous injection. Incidentally it might be remarked that less than a score of years ago the burning question was: Which tuberculin is the best? Now that the reputation of the various tuberculins is equally good—or bad—the controversy has turned on the routes, and the sceptical might be tempted to prophesy that in another decade or two all the routes will be con-

sidered equally good—or bad. The author deals in a perfunctory manner with Friedmann's vaccine, the Deycke-Much partial antigens, and so on, which a text-book cannot ignore, whatever their importance. A whole chapter is allotted to collapse therapy and much space to climatotherapy. Prognosis has a chapter all to itself—that rock on which many a clinical reputation has been built or shattered. Here the author is at his best, as one would expect of a physician with the long and intimate experience of tuberculosis that Dr. Amrein has had in Arosa.

Altogether a sound book greatly to the credit of the author.

LABYRINTH AND EQUILIBRIUM.

By SAMUEL STEEN MAXWELL, M.S., Ph.D., Professor of Physiology in the University of California. London and Philadelphia: J. B. Lippincott Company. 1923. Pp. 163. 10s. 6d.

This book is one of an excellent new series on experimental biology and general physiology, and presents an objective study of the equilibrium reactions of vertebrate animals, with especial reference to the part played in those reactions by the labyrinths. Subjective sensations and clinical applications of the present knowledge of this subject do not fall within the compass of the work. The basis of the account given is the author's own work on the labyrinth, and especially on the otoliths, of the dogfish, but frequent references to the extensive literature of the subject are made. There is also a discussion of the important part played by non-labyrinthine reactions in the orientation of the body; of these the most important are tactile, visual, and kinaesthetic reactions. The chapter on the mechanism of nystagmus is of especial interest. Much work has recently been done on this subject of equilibration and many gaps left by older work have been filled in; the book is, therefore, of considerable scientific value, and clinical applications would not be hard to find.

THE PHYSIOLOGY OF MIND.

An Essay. By FRANCIS X. DERCUM, A.M., M.D., Ph.D., Professor of Nervous and Mental Diseases in the Jefferson Medical College, &c. London and Philadelphia: W. B. Saunders Company. 1922. Pp. 150. 8s. 6d.

THE age-old problem of the interrelation of mind and body attracts the thinker to-day no less than in other generations, when controversies were apt to become somewhat acrimonious, and predispositions, religious and otherwise, were calculated to preclude serious attempts at reaching a solution. Not that in these days bias, conscious or unconscious, is unknown; it is rather that with new morphological, chemical, and physical considerations before him the thinker may make an approach to the question based on wider knowledge than was the case in many well-known instances of other years. We commend to the attention of the philosophically-minded Dr. Dercum's readable essay on the physiology of mind, in which from the standpoint of what would formerly have been dubbed "materialism" the writer endeavours to establish a biological interpretation of mental phenomena. Applying purely physical conceptions, he shows that these phenomena are in their essence physical, and holds that this view is substantiated by the facts of so-called psychophysics. "No neurone, no mind," might be taken to represent somewhat crudely Dr. Dercum's position. Perception, apperception, association, memory, and other processes can be explained by the transmission of impacts through the telencephalon. The collocation by the neurones concerned of the impressions received is thought. That any time at all is required for the response to sense-impressions is in Dr. Dercum's opinion significant as indicating that mental processes are essentially physiological.

INTOXICATIONS.

Traité de pathologie médicale et de thérapeutique appliquée. Vol. XXII. (Intoxications. Maladies de carence. Maladies par agents physiques. Affections médicales et traumatismes.) Published under the direction of EMILE SERGENT, L. RIBADEAU-DUMAS, and L. BABONNEIX. Paris: A. Maloine et Fils. 1922. Pp. 553. Fr. 28.

THIS volume, the twenty-second of a system of medicine of 32 volumes, deals with poisons, deficiency diseases, diseases caused by physical agencies, and localised internal diseases brought to light or aggravated by trauma. In a system of such magnitude, many of the volumes containing 400 to 700 pages, the incompleteness of the volume under review is surprising. A few selected poisons are discussed, some scantily, others in great detail, but more than half the poisons enumerated in British text-books on toxicology receive no mention. It is possible that our interpretation of the word "intoxications" may be broader, but nevertheless a work which includes opium and cocaine should certainly include, for example, veronal and chloral. Corrosive poisons, the majority of the mineral poisons and alkaloids, and most of the so-called synthetic drugs are omitted, except in a general way in the introductory chapter. The apparent want of systematic treatment of the subject has probably come about through the system of a number of different authors each writing separate sections; the principle has many advantages, and in the majority of the separate articles the author concerned has shown himself to be a master of his subject.

The volume concludes with a short account of the deficiency diseases, written mainly from the clinical standpoint, diseases produced by physical agencies, a miscellaneous collection of subjects including frost-bite and sea-sickness, and a chapter on certain diseases, such as tubercle and cancer, which may come to light or be aggravated by trauma.

DE L'AUSCULTATION MÉDIATE.

Translation of Selected Passages from De l'Auscultation Médiate (first edition). By THEOPHILE H. LAENNEC. With a Biography by Sir WILLIAM HALE-WHITE, K.B.E., M.D. Medical Classics Series. London: John Bale, Sons, and Danielsson, Ltd. 1923. Pp. 193. 12s. 6d.

WE recently reviewed an edition of Auenbrugger's "Treatise on Percussion" and now we have before us a portion of the work of his equally illustrious colleague Laennec. To these two men the medical profession, until the discovery of X rays, owed all its capacity for discovering conditions inside the chest cavity, whether morbid or otherwise. Sir W. Hale-White contributes a careful biography of Laennec, who died, by an irony of Fate, from the very disease which his discovery did so much to elucidate and to diagnose—namely, pulmonary phthisis. His monument in bronze stands in the charming old Breton town of Quimper, where he was born in 1781, but he has another more enduring than bronze in the heart of our profession. Sir W. Hale-White's excerpts deal with Laennec's studies of pulmonary conditions only; his observations upon cardiac diseases are not illustrated owing to lack of space. But English readers may be thankful that they possess as much as this book contains of a work which will ever be held to be a classic. It is refreshing to see how generously Laennec recognises the value of Auenbrugger's discovery. Both observers have attained recognition from masters of fiction. Mr. Kipling, as Sir W. Hale-White notes, has written of Laennec as an honoured prisoner of war in England (although he never was there), and every one will remember Dickens's description of percussion, although he does not mention Auenbrugger by name, as used by the incomparable Durdles in *Edwin Drood* and his diagnosis "Solid in hollow; and inside solid, hollow again! There you are! Old 'un crumbled away in stone coffin in vault!"

THE LANCET.

LONDON: SATURDAY, JUNE 23, 1923.

MIDWIFERY WITHOUT TEARS.

WE announced last week the formation of a Departmental Committee¹ by the Scottish Board of Health to investigate the question of puerperal mortality and morbidity, and to suggest remedial measures. Our Berlin Correspondent, in reporting on another page a recent meeting of the Berlin Medical Society, shows how large a share social and economic conditions may have in the matter. But want of skilled personnel hardly accounts for the whole trouble, and without attempting to anticipate the findings of the Scottish Committee, we dare prophesy that too high a proportion of fatality and ill-health will be found attributable to sepsis introduced by the trained accoucheur or midwife. It is time to make a definite attempt to raise the standard of aseptic practice in midwifery as carried out at the patient's home. The main difficulty, we believe, is the distressing contrast between the technique exacted in a hospital or well-equipped maternity home and that which it is possible to achieve in a cottage. The young practitioner, or even the medical student while still on the district, soon gives up the struggle or indeed never properly engages in it. The better his training under surgically clean conditions, the more easily does he get disheartened, for his plight is extremely hard; it is that of the competent billiard-player used to a servile marker and a flawless surface, compelled to play matches for the rest of his life on a cloth untrue, with a twisted cue and elliptical billiard balls, if not—to complete GILBERT'S vivid picture—in a dungeon cell. The outlook seems so hopeless that the practitioner may fail to take even those precautions against infection which he could take without involving much extra trouble or expense, once some convenient adaptation of hospital methods had been thought out.

We commend to the serious consideration of all who have to face these difficulties the technique outlined by Lady BARRETT on page 1279 of our present issue. Sterilised accouchement dressings are put up by instrument-makers in sealed drums or containers, though not by any means generally used, while for the help of the non-affluent the local sanitary authority might reasonably be asked to supply sterile packets containing gown, sheet, towels, and gloves, if there was a general demand for such conveniences. Failing this, ante-natal clinics throughout the country could usefully devote money and energy to this form of service, even if it meant cutting down other less vital activities. Experts in midwifery practice are not likely to complain that the demands made by Lady BARRETT are exorbitant, although they are so much in excess, both in time and in the number and skill of assistants, over those usually available in general practice, that the family doctor may be tempted to dismiss them as impracticable. But the gulf between ideals and actual practice must be boldly faced. The present conditions can hardly be visualised by those in charge of extern depart-

ments or they would at least devise a technique with sterile packages for their own district cases. Probably not 1 in 20 practitioners uses gloves and not 1 in 50 a sterile gown. Not 1 in 100 insists on the patient being shaved, and still fewer employ an anaesthetist throughout the second stage, when, as Lady BARRETT indicates, immediate lacerations might be thereby avoided as well as later painful disabilities—midwifery without tears in either sense of the word.

It is not only an economic question. Many practitioners would protest that such precautions as are advised by Lady BARRETT are wholly unnecessary and that without them results are good enough. That must be determined by figures which are hard to obtain, for it requires courage to notify as puerperal fever every case of fever that occurs in the puerperium, and there is no uniform standard observed as to what is to be notified as fever. Such figures as are available are disquieting and we may expect enlightenment from the Scottish investigation. But the economic question itself is difficult. We do not clearly see how the services of an anaesthetist could be paid for, except in better-class practice, since even the appointment of a full-time official anaesthetist for this purpose alone would hardly suffice a district of any size where two or three practitioners might require his services at the same moment. But whatever the difficulties may be they are not insurmountable. Many of the commoner risks of childbirth will, no doubt, be mitigated by the gradual improvement of ante-natal diagnosis and care, whereby complications—which are for the most part to be foreseen and avoided—are more and more eliminated; labour then becomes the simple, straightforward business of transit of a correctly-placed foetus through a genital canal known to be of sufficient calibre to pass it, when nature can be trusted to do all that is needed. But whatever the foresight observed, sudden complications may arise at any time during childbirth which will require the introduction of the hand or of some instrument into the genital canal, either of which must be frankly regarded as surgical treatment. We do not complain of the fact that practitioners do not attain sterile conditions for this minor obstetric surgery in the poorer homes. That would seem at present to be an impossible task. But we do protest against the attitude, happily becoming daily less common, of regarding such precautions as impracticable and beyond the reach of attainment.

THE BASTARDY AND LEGITIMACY BILLS.

THE medical profession has in one sense no concern with questions of bastardy or legitimacy. When called in to attend a child, a doctor does not first demand to see the mother's marriage lines. But though medical science is not occupied with the registration and enforcement of social verdicts, it cannot ignore their effect upon the unmarried mother's health and peace of mind or upon the child's vitality. Sir GEORGE NEWMAN'S annual reports on the state of the public health have more than once alluded to the well-known difference in death-rate between legitimate and illegitimate children. In 1920, for example, the death-rate of the latter was double that of the former and was shown to decline more slowly during the 12 months of the first year. The difference is attributed to the greater prevalence of disease, to the mother's ill-health and neglect, and to the child's lack of maternal nurture and of home influence. Whatever the causes, the result is a phenomenon which, in the words used by the present Minister of

¹ The Secretary of this Committee, Mr. C. L. Farmer, Scottish Board of Health, Edinburgh, would welcome offers of evidence from medical practitioners.

Health when introducing his Bastardy Bill as a private Member in 1920, accounts for the deaths of thousands and for the permanent lowering of the health of tens of thousands of children. The third reading of the Legitimacy and Bastardy Bills, achieved with less than the usual amount of obstruction on June 15th, will at least help to focus public attention on facts which ought to be disquieting to a country with a social conscience.

So far as legislation is concerned, the English attitude towards illegitimacy has always been severe. There was a famous occasion, in 1235, when the spiritual peers pressed that a bastard child should be regarded as legitimated by the subsequent marriage of its parents and should thus be allowed to inherit property. The earls and barons unanimously replied in a historic phrase that they were not prepared to alter the laws of England. From that day onwards this country has stood almost alone among the nations of Christendom in its attitude. Every year our overseas dominions give fresh adherence to the principle of legitimation by subsequent marriage. If, therefore, Mr. BETTERTON'S Bill passes into law, England will be merely falling into line as she has already done over marriage with a deceased wife's sister and as she will doubtless some day do over the adoption of children and over other social legislation with which the British nations overseas have previously experimented. The strictness of English law, which allowed the illegitimate child neither rights nor duties, neither a father nor a name, has been but little mitigated. Workmen's compensation benefit was long denied. In the case of war allowances and of the grant to unemployed workers' dependents Parliament was not ungenerous, "child" being sometimes defined as including illegitimate child. But on the whole our law of bastardy has moved but little in the last 50 years, except for the institution of "collecting officers" in 1914 (which makes it unnecessary for the woman to have any further communication with the putative father after the affiliation order has been made) and except for the 1918 increases in the amount of the weekly payments under an order, the maximum being raised from 5s. to 10s. It can hardly be maintained that even the new maximum is adequate or that the law is in other respects satisfactory. In effect the mother cannot get an affiliation order before her child is born. After the child is born, if she is not prevented by the restrictions in the law of evidence from getting her order, she may have considerable difficulty in enforcing it. The putative father sometimes manages to elude the jurisdiction altogether; even when liability is established, he may disappear from his last known address or may deprive the woman of payment because he prefers to go to prison for non-compliance with the order. These are some of the obstacles which Captain BOWYER'S Bill seeks to surmount. Its promoters, who, it seems, can now count on Home Office help, have prudently dropped one controversial feature (for registering the name of the alleged father and compelling him at the earliest moment to either admit paternity or clear himself) which appeared in Mr. CHAMBERLAIN'S similar Bill three years ago.

From the point of view of health it is hardly likely that legislation can do as much for the unmarried mother and her child as a progressive expansion of certain aspects of maternity and child welfare work which the public must be educated to support. The word "bastard" has harsh associations. The Labour party succeeded in eliminating it from the Army Act a few weeks ago, though they replaced it with the word "illegitimate,"—five syllables instead of two.

"I suppose," said Mr. LANSBURY on that occasion, "it will be acknowledged that we none of us chose our parents." That simple fact is always worth restating in any discussion on the subject. It is not the child's fault that it is what we call illegitimate. The Labour party at any rate can take credit for its record in seeking to remove the legal and social disabilities imposed upon the bastard child.

MILD SMALL-POX.

AN outbreak of small-pox in the West Country is attracting widespread interest. Fourteen cases were notified at Gloucester on June 12th and four others on June 13th; it is understood that Dr. J. R. BIBBY, medical officer of health for Gloucester, has borrowed a medical officer from a neighbouring municipality to assist in dealing with the epidemic and is co-operating with medical officers from the Ministry of Health. The first case to be recognised as small-pox occurred in Cheltenham and was at first regarded as chicken-pox. Its origin remained undiscovered, but inquiries to which it gave rise revealed a number of cases scattered over the county and beyond its borders, all of which arose about 12 days after a visit to Gloucester, where there now appears to have been a considerable undetected focus of infection. The isolation beds at Longford have now been supplemented by ample accommodation at the Brockworth Aerodrome. We take this opportunity of printing a valuable article by Dr. J. H. GARRETT, medical officer of health for Cheltenham, in which he sets out the features of mild small-pox as they have come personally before his notice in this epidemic. He tells us that the cases are quite commonly being mistaken for chicken-pox or something else upon their first appearance, and the photographs which he has taken may be of assistance to the practitioner in differentiating between the two diseases. The distinction has to be made without the help of constitutional disturbance, which is the first of Dr. W. McC. WANKLYN'S four cardinal points. It is, indeed, a new kind of small-pox which is at present prevalent in this country. The Minister of Health informed an inquirer in the House of Commons on June 5th that none of the 520 cases of small-pox reported in England and Wales during the first three

N.S., not stated.

months of the present year had proved fatal, and he gave the accompanying table, which is instructive enough of the age-incidence of these cases.

The change of type in small-pox is made quite clear from figures furnished the same day by the Minister of Health; in London the small-pox death-rate per 100,000 of population was 36 in 1885 and 28.5 in 1902, whereas since the latter date the death-rate has never exceeded 0.6. Nevertheless, 24 fatal cases of small-pox occurred during 1922 in London and neighbourhood, the numbers being distributed impartially over the various age-groups, only 3 cases being under 10 years of age. In European countries prior to the Great War, the last year with any considerable small-pox death-rate was 1901 in Paris, 1891 in Vienna, and 1912 in Italy. Particulars were also given of cases of small-pox and deaths therefrom in Japan, where notification is compulsory, and showed a high prevalence of a severe form in the years 1917-20.

Prevalence and Fatality of Small-pox in Japan.

Year.	Cases.	Deaths.	Year.	Cases.	Deaths.
1915 ..	17	3	1918 ..	1469	285
1916 ..	266	48	1919 ..	4056	1115
1917 ..	5122	1153	1920 ..	3167	844

The corresponding figures are not available for 1921 and 1922, but up to that time the disease was of a very different character from that prevalent in England at the moment. The fact is, as Dr. GARRETT reminds us, that small-pox, like other infectious diseases, may occur in any degree of severity. America and South Africa have both claimed to be the birth-place of the mild form of small-pox. But whether it is called amaas, alastrim, varioloid-varicella, Kaffir milk-pox, weisse Pocken, or anything else, mild small-pox is still small-pox.

UNITY, PEACE, AND MEDICINE.

THE execution of large mural paintings is a task, quite apart from the question of artistic ability, which has been considered beyond the physical strength of women. Miss Violet Oakley has ignored the difficulties and performed her work in a manner which has gained her recognition among the foremost American painters. Without any indication of unusual physical powers she has been at work on these colossal paintings, some of them 17 ft. high, for the last 20 years, being the first woman to receive the medal of honour from the Architectural League of New York, and the youngest artist ever awarded the gold medal of honour of the Pennsylvania Academy. The pervading idea of a remarkable exhibition now being held at the St. George's Gallery, George-street, Hanover-square, by Miss Oakley and consisting of drawings and colotype reproductions for the great mural paintings for the State Capitol of Pennsylvania, is that unity and peace among the nations is the panacea for every human ill. In an immense panel colour study that embodies her conception of "supreme manifestation of enlightenment in international unity," the figures of a surgeon and a nurse are seen casting scalpel and drugs into the waters that flow from the feet of the figure symbolising unity, to bathe the roots of the trees whose leaves are for the healing of the nations. The accomplishment in draughtsmanship and colour of this artist is noteworthy, but we find her hasty or sanguine when she removes from an ideal vision of a united world the ministrations of medicine, the greatest bond of union between the nations. Unity and peace will not kill disease; but with unity and peace there will come concerted action against disease, and in such coöperative efforts the various nations will find the readiest means of development and consolidating mutual goodwill.

Annotations.

"Ne quid nimis."

OXIDATION IN THE LIVING CELL.

THE days are rapidly drawing to a close when the teacher of chemical physiology can dismiss the later stages of metabolism by the satisfying statement that the substances under consideration are oxidised to carbonic acid and water. In the past anabolism has been very carefully considered and students have been taught at great length the mechanism of building up fats and carbohydrates. Katabolism, however, has been neglected, amino-acids are dismissed from thought after deamination, fats and carbohydrates are banished by that all-covering statement "they are oxidised to CO₂ and H₂O." Prof. F. G. Hopkins, in one of an admirable series of lectures delivered at St. Mary's Institute of Pathology and Research, which appears in the front of our present issue, calls attention to the vast amount of work now accumulating on the later stages of disintegration of the more complex substances produced in the body. All these processes involve two essential chemical actions, either oxidation or reduction, and, as Prof. Hopkins points out, the answers to all katabolic questions are to be found actually in the study of these processes. Oxidation, as defined by chemists, means an increase in the non-metallic or electro-negative part of a compound, whilst reduction means the opposite. From the biological standpoint, the definition really reduces itself down to the giving or taking away of oxygen. On the face of it, the question seems very simple. Carbon monoxide burns in oxygen to produce carbon dioxide—a simple example with no apparent difficulty. However, it has been shown that perfectly dry oxygen and perfectly dry carbon monoxide cannot be made to combine, and that water is essential to the process, and this applies to practically all other oxidations. Another complication was demonstrated by Wieland, who showed that even free oxygen was not necessary, since, by using platinum-black and damp carbon monoxide, carbon dioxide and free hydrogen were produced. Finally, v. Wartenburg and Sieg published in 1920 their scheme of the burning of carbon monoxide in oxygen; there is nothing imaginative about this scheme, for all the bodies appearing in it have been actually isolated.

When such an apparently simple process proves to be so complex we may well wonder as to what the steps may be in the biological oxidation of such a substance as glucose.

From the above example we may illustrate the principle of Prof. Hopkins's lecture. Firstly, free oxygen is not necessary, the oxygen contained in the water molecule being able to take its place. Water, as is well known, exists in an ionised form—namely, H.OH. If the oxygen is to be given up, something must absorb or take up the hydrogen—viz., a hydrogen acceptor, the substance oxidised being regarded as an oxygen acceptor. As it is very difficult chemically to break up the OH group, there must be some substance, a catalyst, which enables this to be done. Such a body, facilitating the transport of oxygen or CO₂, would be essential to life. Hitherto nebulous bodies called oxidases and peroxidases have been credited with this feat, but thanks to the work of Prof. Hopkins, an exact chemical composition can now be assigned to at least one of them—viz., glutathione. This substance is capable of acting in a catalytic manner, and carrying separate O and H atoms ready for use. The importance of this step in knowledge is very great, since it reclaims the oxidases from the kingdom of bodies of "unknown constitution." By means of this compound, unsaturated fats can be rapidly oxidised at

body temperature. The busy practitioner may ask, How much better off are we for knowing these facts; what application have they to disease and its treatment? It is no exaggeration to say that an entirely new field of treatment can be seen in the near future, and the following example will bring home the importance of the new observations. Let us consider what is loosely included under the term acidosis, a common and serious enough condition to warrant the practitioner's close attention. Leaving out controversial points, we are justified in saying that the common clinical form of acidosis, whether a result of delayed chloroform poisoning, toxæmia of pregnancy, or diabetes, is a ketosis—that is to say, it is due to the presence of certain fatty acids. In normal metabolism the complicated fatty acids, such as stearic and palmitic acids, are desaturated and carbon atoms are oxidised away, two at each step, until the compound is reduced from 18 carbon atoms to 2 or 3, which in their turn disappear in the form of CO_2 and water. In acidosis, however, the oxidative processes are deficient, with the result that the degradation stops at the 4-carbon-atom stage. Derivatives of butyric acid, such as β -oxy-butyric acid and aceto-acetic acid, circulate and produce the symptoms of acidosis. Now, the degradation of these fatty acids is accomplished by desaturation and oxidation, both oxidative processes, and presumably both dependent on some body such as glutathione.

It is not going too far to suggest that acidosis in the future will be controlled clinically by the administration of some such substance, and in any case investigations on Prof. Hopkins's lines are bound to throw light on the treatment of this condition. The inborn errors of metabolism afford further examples. Research on oxidative catalysts may cure cystinuria, which is merely an expression of lack of oxidation. Prof. Hopkins could have chosen no more topical subject for his lecture, quite apart from the fact that it is to his particular interest and personal work in this branch of medicine that our progress has been largely due.

CHINA'S LEGITIMATE DRUG NEEDS.

THE proceedings of the League of Nations Opium Committee at Geneva during the past weeks and their attempt to find out the world's medical requirements of morphia and cocaine give importance to a pamphlet just issued by the International Anti-Opium Association of Peking, in which the secretary of the Association, Dr. W. H. Graham Aspland, makes an attempt to formulate an estimate of the yearly amount of narcotic drugs required for medical use in China. Dr. Aspland, who was for many years professor of obstetrics at Peking University Medical School and president of the North China Medical Association, recognises the extreme difficulty of getting accurate data, and his own figures are based upon calculations made from details supplied mainly from the mission hospitals and dispensaries, of which there are 709 in China, employing 657 foreign and Chinese doctors, and treating annually about 1,400,000 patients. Replies to his questionnaire were received from hospitals and dispensaries representing a yearly treatment of 850,000 patients. The sickness incidence of China was calculated at 5 per cent. "It may be higher but it certainly cannot be lower," says Dr. Aspland. "In European countries it is considerably lower and in U.S.A. only 2 to 2.5 per cent. Now if we may work on this hypothesis, then China, with 400,000,000 people, ought to have a sickness incidence of 20,000,000 yearly, and presuming that all these sick people were under treatment by qualified doctors either in homes, hospitals, or dispensaries, then according to our estimate of 15 g. per thousand patients based on the statistics already dealt with, a total of 300,000 g. or 10,000 oz. of morphia and narcotics would be required." However, in reporting to the League of Nations Dr. Aspland says that it was thought advisable to double this amount in order to cover all contingencies, for with an increasing medical profession

more narcotics would be scientifically used. A moderate estimate of the present illicit traffic in drugs cannot be less than 30 times that of the suggested medical requirements on the generous basis outlined. As regards cocaine, Dr. Aspland's estimate of the total yearly requirements for China is 2000 oz. "It is not proposed to leave any margin, for except in the hands of qualified doctors there cannot be other than addictive use."

In a supplementary letter which we have seen Dr. Aspland gives some figures regarding the seizures in the Customs during 1922. The amount taken at Shanghai, Tientsin, Peking, and Shansi amounted to 80,000 oz. The seizures of narcotics in the Shanghai Customs for the quarter ending March, 1923, alone show over 3000 oz. originally manufactured in Germany, 464 oz. from London, and 176 oz. from France. This does not, of course, imply that the drug in the first instance was not perfectly justifiably sold under licence to a purchaser, who subsequently dealt in it in an illicit manner.

SELECTION OF OPERATION FOR GLAUCOMA.

THE operative treatment of glaucoma has for many years been debatable ground for ophthalmic surgeons. The object of all operations is to provide a freer exit for the intra-ocular fluid and so bring down the intra-ocular tension. The classical operation of iridectomy attempts to do this by opening up the angle of the anterior chamber and so providing an easier access to the lymph channel known as Schlemm's canal, which lies near the junction of cornea and sclerotic. It was very soon recognised, however, that only in acute cases and in those chronic cases where the angle of the anterior chamber was not much altered by the growth of fibrous tissue, was this operation very successful, and, further, it was noticed that in many cases where the operation was faultily performed from the surgical point of view, leaving a tag of iris entangled in the scar, the result in stopping the glaucomatous process was far better than in other cases where no fault could be found with the surgical technique. The reason was found to be that in the operation where the iris was entangled the scar became permeable, and the drainage, which was insufficient through Schlemm's canal, was supplemented by drainage into the sub-conjunctival space. Unfortunately, this method of obtaining drainage—by unprotected iris prolapse—was by no means a safe one, for it afforded a possible channel for septic infection and was even sometimes followed by sympathetic irido-cyclitis. Hence it has come about that many minds have been turned to the problem of how to afford a safe passage for the intra-ocular fluid into the subconjunctival space. The earliest attempt was a simple incision through the sclera, an operation which had its vogue for many years, but the scar that follows is in most cases only temporarily permeable, and this operation is now seldom performed. Colonel H. Herbert was one of the pioneers of more efficient procedures, and in a recently published volume¹ he describes two of his earlier methods, each of which is still practised by some of his followers. These are the "wedge isolation" operation and the "small-flap sclerotomy"; the latter was very popular a few years ago and is still almost exclusively practised by some surgeons. Colonel Herbert himself, however, has made what he considers an important advance by his present operation, in which a tag of iris is deliberately included in a scleral scar, the whole operation being performed subconjunctivally. This operation has now been advocated by him for a good many years and has brought him into sharp conflict with the advocates of the more generally performed operation devised by Colonel R. H. Elliot, sclero-corneal trephining. "Deliberate iris-inclusion," he says, "has never made the least headway in this country; it has hardly made a

¹ The Operative Treatment of Glaucoma. By H. Herbert, F.R.C.S. Eng., Lieut.-Colonel, Indian Medical Service (retd.); Consulting Surgeon to the Nottingham and Midland Eye Infirmary, &c. London: Baillière, Tindall, and Cox, 1923. Pp. 152. 10s. 6d.

beginning. This is due to a series of misapprehensions." To dispel these misapprehensions is the main object of his book. The fact that an unprotected prolapse of the iris is dangerous is, in his view, no argument that a protected one is so. There is no doubt, he says, that this question of effective conjunctival covering is the main one. That early infective danger is a grave objection he admits, but only in the absence of the necessary precautionary measures. On the other hand, this form of treatment is definitely put forward as the most promising means of abolishing late infection in the higher-grade glaucomas. It is true that a certain number of surgeons of late years have abandoned the operation of trephining on this very ground of the danger of late infection. It will be enough here to indicate that arguments in favour of a rival procedure can be found in this book. In Colonel Herbert's view a conjunctival fistula such as is provided by the trephining operation is dangerous if it causes a localised conjunctival bleb over the trephine hole. In his own operation his aim is to avoid all trace of conjunctival vesiculation. Colonel Herbert's operation has already given rise to a good deal of debate and is not likely to be generally adopted without further controversy. It is at any rate a gain that his views should be made easily accessible to all who desire either to test or to criticise their soundness.

RINDERPEST IN INDIA.

CATTLE plague has frequently decimated herds in India to the extent of 40 per cent. Mr. W. A. Pool and Mr. T. M. Doyle, veterinary surgeons, of the Imperial Bacteriological Laboratory, Muktesar, have been studying means of prevention; for over 20 years the method of inoculation with serum alone has been used, answering its purpose fairly well, but falling far short of real efficiency, and these investigators have been testing the efficacy of what is known as the "serum simultaneous" method, which consists of subcutaneous injection of a small amount of virulent cattle plague blood on one side of the animal and on the other a suitable dose of antiserum. Over 450,000 cattle have been inoculated by this method, and the mortality-rate from all causes has only been 0.98 per cent. It has been found that cattle were immune for long periods, up to a year and even six years after inoculation. The economic aspect of outbreaks of rinderpest is serious; abortions and deaths of cows arise, and the losses of milk-supply and dislocation of agricultural operations at critical seasons are considerable. In India methods for the control of disease must be made as popular as possible, especially where cattle are concerned. In reporting their work Mr. Pool and Mr. Doyle consider¹ that sufficient experience has now been gained to warrant a start with the simultaneous method on a small scale in each province, and suggest that compensation should be paid to the owners of animals that die as a result of the inoculation.

MULTIPLE PEPTIC ULCERS.

In a paper read before the annual meeting of the Radiological Society of North America Dr. Miller M. Portis and Dr. Sidney A. Portis,² of Chicago, who report two illustrative cases, state that before the introduction of X rays the diagnosis of more than one peptic ulcer occurring at the same time was made only in the operation room or in the dead-house, whereas at present this diagnosis can be made with accuracy before operation. The following statistics given by various pathologists and clinicians are quoted, relating to the frequency of multiple peptic ulcers. Rokitsansky found that among his 79 cases of gastric ulcer no fewer than 17, or about 20 per cent., showed two or more open ulcers post mortem. In a

series of 638 cases of gastric ulcer at the Mayo Clinic 28, or 4½ per cent., had more than one ulcer present. Fenwick, in an analysis of 867 post-mortem records of gastric ulcer, found that one ulcer was present in 80.5 per cent., two in 12.1 per cent., three in 3.1 per cent., and four or more in 4.2 per cent. According to Fenwick, chronic gastric ulcer is multiple in 13 per cent. of all cases, while acute ulcer is multiple in 50 per cent. On the other hand, Goldschmid, in a review of 1300 autopsies at Frankfurt, among which there were 25 gastric and 21 duodenal ulcers, did not observe a single case with more than one ulcer present. In rare instances an excessive number of gastric ulcers is found—e.g., 60 (Hewitt), 34 (Osler)—or they may even be too numerous to count (Lange). Such cases are usually associated with septic infection or secondary syphilis. Duodenal ulcer, though usually solitary like gastric ulcer, may be multiple. Carman reported that among 139 cases of gastric ulcer, and 490 of duodenal ulcer, operated on in the Mayo Clinic in 1916 an ulcer was found both in the duodenum and stomach in 16 instances. The histology of multiple peptic ulcers resembles that of the single gastric or duodenal ulcer. The first of the two cases reported by the present writers occurred in a woman aged 54, who had been suffering from gastric trouble for years, with acute symptoms of eight weeks' duration. X rays showed two penetrating ulcers in the lesser curvature, and their presence was confirmed at the operation, when they were resected and the stomach anastomosed to the jejunum. The gall-bladder, which was full of stones, was removed at the same time. The patient made a good recovery. In the second case, which occurred in a woman aged 43, the X rays showed two ulcers on the lesser curvature and some deformity of the duodenal bulb. Posterior followed by anterior gastro-enterostomy was performed with some relief of the symptoms.

ATTACKS ON ALIENISTS BY THE INSANE.

ON March 6th last Dr. K. O. Olander, the distinguished Swedish alienist, was assassinated outside his house in Stockholm by an insane patient, who emptied his revolver into Dr. Olander's chest, killing him instantly. Taken by itself, this incident was not particularly extraordinary, and it was certainly not unique. As Prof. Laehr has shown in his work "Gedenktage der Psychiatrie," the toll taken by the insane from the medical profession runs into hundreds, and the risk of assassination taken by the medical profession in general, and alienists in particular, is one with which every educated person is familiar. But there were certain attendant circumstances in the case of Dr. Olander's assassination which merit comment. Some years ago Dr. Olander and a colleague were requested to investigate the mental state of a banker who had accused two banks of nefarious actions, and who was a notoriously refractory and dangerous person. Dr. Olander and his colleague, Dr. Bilström, were concealed in a room in which this patient and another banker had a conversation, and on the strength of what the alienists heard the suspect banker was certified as insane. It transpired that he carried a loaded revolver, and that it would have been impossible to investigate his mental condition by more direct methods. The procedure adopted in this case was, however, censured by the medical authorities, and, most unfortunately, this censure was published in the lay press a few days before Dr. Olander's assassination. The inquiry which followed it showed that the murderer had read this censure. Naturally these circumstances have raised a storm of protest from the Swedish medical profession, and the fact that the official censure of Dr. Olander's action was not intended by the medical authorities for publication in the lay press has only partially exonerated them from blame. Dr. Olander's many medical friends are collecting a fund, the proceeds of which will first be devoted to the education of his two children and will later be devoted to some permanent memorial. So much for the more or less personal aspect of this case. It has, however,

¹ Memoirs of the Department of Agriculture in India: Studies in Rinderpest. By W. A. Pool and T. M. Doyle, Agricultural Research Institute, Pusa.

² Journal of Radiology, May, 1923.

much more than a personal interest, and in Sweden, at any rate, it is likely to lead to far-reaching reforms with regard to lunacy legislation. It is obvious that alienists need more protection than they have hitherto been given; theirs is already a peculiarly difficult task, they are threatened on one side by irresponsible lunatics, and on the other side by bureaucratic authorities whose sense of responsibility to the insane and the letter of the law is apt to expose alienists to unnecessary risks. This case is also a sad example of the mischief the public press can make when it gives publicity to a subject that should either be ignored entirely or handled with great discretion.

SPONTANEOUS PNEUMOTHORAX IN PULMONARY TUBERCULOSIS.

EXTENSIVE or complete spontaneous pneumothorax is so dramatic, and usually so serious a complication in pulmonary tuberculosis, that its occurrence is at once recognised, while its grave effect upon the course of the disease is well known. On the other hand, in certain cases, a spontaneous escape of air into the pleural space may be the first indication of the presence of the disease, and provided that no infection of the pleura results and that the perforation of the pleural membrane closes quickly, recovery may be rapid and complete. It is well recognised that partial pneumothorax, of a degree sufficient to be apparent on X ray examination, yet giving only equivocal physical signs, may occur; but this pathological incident is usually regarded as uncommon. A monograph¹ by Dr. Nathan Barlow and Dr. James C. Thompson, which has lately been published under the ægis of the United States Public Health Service, sheds new light on the matter. The authors' chief thesis is that small pneumothoraces are so common that almost every patient suffering from pulmonary tuberculosis develops them sooner or later, and that they modify or even completely change the physical and X ray signs, the clinical symptoms, and the course of the disease. For the past two years Dr. Barlow has been engaged solely in the examination of physical signs, while Dr. Thompson has been chiefly occupied in reading and recording chest skiagrams. When there were discrepancies between the clinical and X ray findings, the patients and the skiagrams were confronted with each other, and a combined effort was made to find the cause of the conflicting interpretations. This work was carried out in an army hospital at New Haven, Conn., and in a series of 1000 patients there were 525 suffering from tuberculosis, and 475 from chronic non-tuberculous pulmonary disease which, in most cases, represented the relics of poison gas and influenza. Among the 525 cases of tuberculosis there were 189, or 36 per cent., in whom no small pneumothorax could be found; among the remainder from one to six small pneumothoraces were demonstrable in each case. Among the cases in which the tuberculosis was active and progressive, 75 per cent. showed one or more small pneumothoraces. In 25 cases necropsies were performed and opportunities afforded for observing the changes associated with previously demonstrated localised pneumothorax. Not only the number of these small pneumothoraces, but also their behaviour, is amazing. They come and go with extraordinary rapidity, and after complete closure of the opening in the lung "the absorption of the air in small pneumothoraces is a matter of hours only." Any small pneumothorax will disappear in less than six weeks after the underlying tissue has healed to a sufficient degree to withstand the negative pressure of the pleural cavity.

In the chapter on X ray appearances it is pointed out that by the usual technique for examination of the lungs, the perception of a small pneumothorax is usually impossible. The authors take two stereoscopic plates with different times of exposure. When fused in the stereoscope, the dark plate predominates in the

picture and gives penetration and contrast. The light plate carries the detail to the pleura in the central part and nearly to the pleura in the lateral part if the lung is normal. The principal X ray signs indicative of a localised pneumothorax are the following: (1) Compressed or collapsed lung tissue; (2) areas of rarefaction; (3) pleural cusps; (4) deviation of neighbouring or distant structures; (5) deviation of the trachea, mediastinum, heart, or diaphragm; (6) atypical position of densities, course of bronchi or distribution of fibrosis; (7) annular shadows; and (8) localised fluid levels evidently not in cavities. It appears that these signs, with the exception of the localised fluid level and certain kinds of annular shadow, are more frequently due to localised pneumothorax than to any other cause. They are often conspicuous, and, if not understood, may lead to diagnostic mistakes. Suddenly unexplained improvement in a case of pulmonary tuberculosis—the false recovery of Laennec—is, in the authors' opinion, usually due to a localised pneumothorax favourably influencing a considerable part of the diseased lung. As a rule, a localised pneumothorax has a favourable effect, at least for some time. But it is indicative of active disease, and it is dangerous because it lulls the patient and his physician into a false sense of security. The authors make the following bold claim which is based on a study of readmission cases due to relapse of the disease:—

"As we have just shown, 16 per cent. of all admissions were readmissions for relapse, 80 per cent. of whom have had more or less effective collapse of the entire lesion. It can readily be seen that it is probable that the great majority of patients who are discharged with pulmonary lesions which are apparently inactive because collapsed by localised pneumothoraces will relapse, and that the retention of such patients under treatment will prevent about 80 per cent. of the relapses, which occur within the first year after discharge. . . ."

An inevitable corollary to these views is the advice that no patient with a localised pneumothorax should be discharged from an institution. The interesting calculation is made that, in general, a localised pneumothorax can permit partial collapse of from four to eight times its own bulk of lung tissue. The authors conclude with a short note on the induction of a partial pneumothorax as a therapeutic measure. They regard as a most important contra-indication to treatment with complete artificial pneumothorax the almost entire suppression of signs of moisture on the other side by one or more small pneumothoraces.

This brief résumé of the work of Dr. Barlow and Dr. Thompson will be enough to stimulate the interest of all concerned in the treatment of tuberculosis. Within the 260 pages of the bulletin the authors marshal a host of cogent arguments in favour of their views.

STREPTOCOCCI IN STRANGLES.

THE problem of streptococcus classification is not only one of perennial interest from the purely systematic point of view but also one of much importance practically, since it bears profoundly upon the possibilities and technique of specific therapy in streptococcal infections. In general, the many schemes of classification which have been propounded have shown that it is usually possible to place a strain of the organism in one or other of the existing groups when its characters are examined soon after isolation. Certain of these groups are better defined than others, and the organisms comprising them have characters of a more permanent kind; such, for example, is the enterococcus group.¹ The significance and value of many of the other proposed groups are doubtful. The general theory of streptococcal infections appearing as such widely different clinical types is that the lesion resulting from an infection is dependent both upon the site of infection and the particular grade of virulence with which the streptococcus in question is endowed. If we had means of

¹ Bulletin Nr. 132, Government Printing Office, Washington.

¹ J. H. Dible: The Enterococcus and the Streptococcus Fæcalis, Journal of Path. and Bact., 1921, vol. xxiv.

recognising such subtle differences in virulence we might easily solve the problem, but these are lacking, and research has not yet demonstrated with any constancy the presence of more easily examined associated properties which would serve as well. It is of interest, therefore, to find a claim put forward by MM. Brocq-Rousseau, Forgeot, and A. Urbain² to have differentiated the streptococcus of a specific type of infection—strangles in horses—from morphologically similar strains met with in man and in other animal diseases. This they claim to have done by complement-fixation tests; a method which has so far failed to advance the general problem of the classification of the human-infesting strains. In a former paper their results show a constant fixation of complement by streptococci from strangles in the presence of what is presumably a polyvalent serum; streptococci from other animal sources, and from the human subject, gave negative results. In a more recent paper,³ the same investigators have pursued the subject by inquiring if these characters, which distinguish the streptococcus of strangles, are constant, or if, resultant upon changes in environment, they may become modified or lost. Besredka holds that by animal passage a streptococcus loses its identity and, becoming adapted to the animal body upon which the passage is made, acquires a new individuality. The experiments in this direction show this to be the case with the organisms for strangles, so that after a certain number of passages, be it upon mice, guinea-pigs, or rabbits, the ability to fix complement in the presence of the specific serum is lost. It is always possible in such cases that the original strain has become replaced by one proper to the animal experimented upon—a fallacy to be borne in mind in such work—but in this case the fixative power shows a gradual extinction, suggestive of a progressive modification of the organism in question. On the other hand, on ordinary culture-media the original characters of the organisms are preserved. These results are of considerable interest in their bearing upon the general problems of the streptococcus in the human subject.

MANCHESTER RADIIUM INSTITUTE.

THE report on the work of the Manchester and District Radium Institute for the year 1922, by Dr. Arthur Burrows, contains the record of the first completed year in the new building. Just short of 800 cases presented themselves for treatment, while the full capacity of the emanation plant was utilised, more than 500 emanation plates and 1250 emanation tubes being made during the year. Forty-one out of 85 cases of rodent ulcer treated were apparently cured. Exclusive of rodent ulcer, 59 cases of malignant disease, out of a total of 584, were rendered free from signs and symptoms of disease, thus maintaining the "usual average" of slightly over 10 per cent. of perfect immediate results following upon radium treatment. The types of carcinoma in which treatment is most gratifying are those affecting the cervix uteri and the mouth. The conclusion is reached in the report that dense fibrosis has no great influence on the specific gravity of tumours and therefore exerts little, if any, screening effect. Improvements have been made during the year in the arrangement for protecting the workers in the Institute, illustrations being given in the report of the various devices. A new diathermy apparatus has been installed with a view to combining its use with that of radium. Mention is made in the report of a special study by Dr. J. Holker on the physical chemistry of serum in health and disease, with special reference to the effect of alpha, beta, and gamma rays on serum. By this means it is hoped to throw light upon the general systemic effects which follow radiation and to obtain some indication of the degree of absorption of tumours undergoing ray treatment. The report, although tantalisingly brief, will be read with

interest by other workers in the same field; the results already achieved more than justify the generosity of Sir Edward Holt in presenting to Manchester its admirable Radium Institute.

SUCCESSFUL INSULIN MEDICATION.

THOSE who have not actually seen the change in a suitably chosen case of diabetes after insulin administration may hesitate to involve themselves or their patients in the mesh of expensive and elaborate biochemical tests which must accompany and control this treatment. For their comfort and encouragement we reproduce here two photographs of the same child, the interval between them being only two and a half months, before and during treatment. The first photo was taken on Dec. 7th, 1922, when the boy weighed only 15 lb., having had diabetes for two years. At this period, even with days of complete starvation, he had

Child with Diabetes Treated with Insulin.

Feb. 26th, 1923.

glycosuria unless his diet was restricted to 5 per cent. vegetables. He was first put on insulin treatment at the St. Louis Children's Hospital under the care of Dr. W. McKim Marriott; in four days the sugar in the urine fell from over 40 g. a day to nil, while the blood-sugar fell from 400 to 100 mg. per 100 c.cm. in eight days. At the time of the second photo, Feb. 26th, 1923, the weight had increased to 30 lb. and the patient was on a diet of 55 g. carbohydrate, 85 g. protein, and 100 g. fat. Two months later he weighed 32 lb. During three months of treatment it was found possible to reduce the daily dosage of insulin to 15 units. We have but briefly summarised the data given by Dr. Ralph H. Major in the *Journal of the American Medical Association* for June 2nd, where the photos are published. Dr. Major gives only a short account of the case, but the pictures speak for themselves, and form a most convincing proof of the desirability of undertaking all the work still inseparable from insulin treatment in cases judged suitable therefor.

PROGRESS IN COMBATING VENEREAL DISEASE.

IN spite of reduced resources, it is recorded in the annual report of the National Council for Combating Venereal Diseases, presented on June 13th at the annual business meeting, that the volume of propaganda has increased rather than diminished. The formation during the past year of the Union Internationale contre le Péril Vénérien, on which all national organisations for combating venereal diseases are represented, is noted as an encouraging feature. The work considered by the Union as of immediate importance is: (1) Rendering non-infective the maritime and colonial

² MM. Brocq-Rousseau, Forgeot, et A. Urbain: Etudes sur le streptocoque gourmeux, *Annales de l'Institut Pasteur*, t. xxxvi., September, 1922.

³ Ibid., March, 1923.

services; (2) surveillance of emigration; (3) surveillance and concerted action along the frontiers; (4) international measures for the suppression of quackery; (5) a single moral standard for both sexes; (6) the study of the principle of legal responsibility, compulsory notification and treatment, penalties, &c. It is hoped that through the agency of this organisation adequate international machinery to secure the continuation of treatment for migrants will be adequately dealt with. Increased attention is being given in all countries to the problem of how the rising generation may be best instructed in the biological facts of life and in sex hygiene. As to the measures taken in this country, it is considered satisfactory that the fall in the number of new cases at the free treatment centres from 105,000 in 1920 to 84,000 in 1921 has continued, since in 1922 only 73,000 new cases presented themselves. There are, however, grounds for believing that a very large number of infected women are not seeking treatment. In order to help to overcome this difficulty it is suggested by the Council that infant welfare centres should provide facilities for diagnosis and that special arrangements for the treatment of patients passed on from infant welfare centres should be made at the venereal disease treatment centres. General approval is expressed by the council of the policy outlined in the report of the Trevithin Committee.

A SCHEME FOR A COUNTY PATHOLOGIST.

REPRESENTATIVES of the voluntary hospitals of the County of Dorset and of Yeovil met on June 5th at the Dorset County Hospital to discuss a scheme for the appointment of a pathologist for Dorset voluntary hospitals. The purpose of the scheme was to centralise the pathological work of the county, to provide a rapid means of obtaining reports on cases, and to enable practitioners in the county to obtain the immediate services of a pathologist and bacteriologist. The idea was for the pathologist to attend at a laboratory put at his disposal at the Dorset County Hospital, at stated hours each week-day, receiving an honorarium from the hospitals at an agreed sum *per capita* of all in-patients and at the same rate for those out-patients who required his services, and being free to take fees for private practice in consultation with practitioners. The out-of-pocket expenses of the laboratory were to be paid for by the pathologist, who was to be appointed after consultation with the professor of pathology at the University of Bristol. The scheme, as thus outlined, was unanimously approved in principle by the representatives, who undertook to present it for consideration by the various governing bodies of the hospitals, the capitation fee proposed being 2s. per head. Considerable doubt was expressed, however, whether the hospitals would undertake to pay such a levy. Even this sum was estimated to bring in an income of only £300 per annum, and, as Prof. Walker Hall pointed out in his letter accepting the invitation to coöperate in the nomination of the pathologist, the amount of honorarium available would be the determining factor in the type of pathologist likely to present himself for the appointment. During the first few years, however, the pathologist could not expect to obtain much from private fees, and Prof. Walker Hall suggested the deletion of the clause requiring out-of-pocket expenses to be paid for by him; Prof. Hall even foresaw the necessity of the provision of a competent laboratory assistant. Although the finance may present difficulties at the moment, we sincerely hope that any workable scheme to provide better facilities for pathological investigations in county districts will not be turned down without serious consideration. It is noticeable from reports of various voluntary hospital committees set up by request of the Voluntary Hospitals Commission to investigate conditions in the several areas, that while the large hospitals providing accessory departments such as X ray, pathological laboratories, and so forth, lack sufficient funds to carry on, the smaller hospitals, where no such facilities are provided, often have a

credit balance. The remedy might be a county financial fund allocating grants of money in accordance with work done. Pooling of special departments is not easy, but a beginning might be made on the lines suggested in Dorset, and we shall watch with interest the fate of the scheme we have outlined.

HARVEIAN SOCIETY: THE ANNUAL DINNER.

THE annual dinner of the Harveian Society, held at the Connaught Rooms on June 14th, with Sir Crisp English, the President, in the chair, was a successful and pleasant function. The company of about 150 people included a number of guests distinguished in law, literature, or politics, as well as in medicine. After the loyal toasts had been honoured, Mr. G. K. Chesterton proposed the toast of the Society. As a journalist, Mr. Chesterton said, he had little reason to be proud of the methods of journalism when applied to medical or scientific subjects. The lay journalist was apt to seize upon one sentence of a scientific address or discussion shorn of its context, and from this to elaborate an article for the public with scare headlines. For instance, he could imagine that in a discussion upon baldness one expert might make use of a phrase such as "if all these conditions should operate simultaneously and unchecked, it would appear that the loss of hair would be inevitable." The last part of this sentence would form the text of a newspaper article with headlines such as "Mankind Condemned to Baldness—Science Predicts a Bald Humanity." "Science" (always "she" in the newspapers) was in this fashion made responsible for the most unwarrantable claims or unfounded assertions; "Science" was reported as having said "something" when, in fact, the statement was made by one individual who might, and often did, hold views diametrically opposed to those of the rest of his fellow scientists; an enthusiastic theory that was far in advance of established fact was often served out to the lay reader as the "latest achievement of science." In an age of advertisement, which he was convinced that past and future generations would regard with surprise, the medical profession was one of the few that retained its sanity by refusing to join in this almost universal desire for notoriety. In his reply, Sir Crisp English, after mentioning that on its ninety-second birthday the Harveian Society was in a flourishing condition, referred to the many problems that confronted the Society both as medical men and as citizens, notably those of cancer, tubercle, and housing. Sir StClair Thomson proposed the toast of the sister societies in an amusing speech and Sir William Hale-White replied. The health of the guests was proposed by Dr. Charles Buttar. In his response, Lord Montagu of Beaulieu compared the function of roads to that of arteries in the body in that any obstruction led to congestion and congestion to decay. Sir Anthony Hope Hawkins, who alluded to medical men distinguished in literature—Smollett, Conan Doyle, and Somerset Maugham—and Sir Richard Muir, who made an amusing reference to the spectacle of a great medical expert witness in the box being cross-examined by an even greater medical expert in the dock, also responded.

THE GUARDIANSHIP SOCIETY.

A STILL further increase in the work of this Society was reported at the annual meeting, held at Brighton on June 11th. The special object of the Society is the care and supervision of the mentally and physically defective by boarding them out in carefully chosen families, by assisting them to obtain training and employment suited to their capabilities, and by visiting them and taking a friendly interest in their moral and material welfare. This type of work is done by no other society in the country. The annual report shows that the number of fresh applications during the year was 317 against 284 in the previous year, but the number of fresh cases actually taken was 156 against 163. The total number of patients cared for was 386, and the number remaining at the end

of the year was 243, against 371 and 231 respectively. Seventy-four of the cases had been certified cases—71 under the Mental Deficiency Act, and three under the Lunacy Act. There had also been 58 cases under supervision in their own homes for the Brighton Corporation. Cases had been received from 53 public bodies, 24 societies, hospitals, &c., and 57 from private sources. The scope of the industrial class has lately been increased; this class is now held daily and a special teacher has been engaged. Dr. Duncan Forbes, medical officer of health for Brighton, expresses the hope (see p. 1286) that a grant will be forthcoming for this educational work. In addition arrangements are in progress for a class to be held twice weekly for boot-repairing. The report goes on to say that the question of starting a hostel for feeble-minded boys, where they could go out to daily work under supervision and help to support themselves, had been raised, but such a scheme needed much consideration. A trained nurse has been appointed to visit patients in Brighton, and another such visitor is needed to help in the country, where patients were so scattered. The statement of accounts showed receipts amounting to £8633 8s. 8d., of which all had been spent excepting £1 15s. The report and accounts were passed, after which a large committee was elected, the co-opted members comprising representatives of the Brighton Corporation Mental Deficiency Act Committee, the Hastings Corporation Tubercular Care Committee, the London County Council, and the Brighton Education Committee and Board of Guardians. An address on the Guardianship and Its Aims was given by Dr. Helen Boyle. She said that people of this country appeared to have been rather obsessed with the idea that if they had good buildings and good food for their afflicted children they had all that was necessary. They did not realise that what was most important was home care; Miss Woodhead, who was a pioneer in that movement, had realised the need. Children were sent by boards of guardians all over the country and it seemed rather absurd they should have to come to Brighton when the homes they required could, of course, be found much nearer. A great many homes got so fond of the poor little creatures boarded-out in them that even if the money was not always forthcoming they were still content to carry on. While they might get love, devotion, and self-sacrifice in institutions, said Dr. Boyle, it was impossible for a matron to bestow the same affection upon 30 children as a mother could bestow upon three or four. Apart from the friendly supervision over these less gifted creatures, the Society did everything possible to find suitable occupations for them, and it was hoped that a grant would be secured for the occupation centre which had been started, and that it would enjoy the support such centres received in other parts of the country. Dr. Boyle's address and one by Dr. Francis H. Edwards on Mind and Matter were greatly appreciated by those present.

AN important debate on the Surgery of the Hepatic and Common Bile-ducts will be opened by Dr. William Mayo, of Rochester (Minnesota), at the Surgical Section of the Royal Society of Medicine, on Wednesday, June 27th, at 5.30 p.m. Sir Berkeley Moynihan, Mr. James Sherren, Mr. Grey Turner, and Mr. A. J. Walton will take part in the discussion, each dealing with a particular aspect of the subject. A large exhibition of specimens illustrating the pathology and surgery of the bile-ducts, kindly loaned by various metropolitan museums and arranged by Mr. James Berry, President of the Section, will be on view in the lecture-room during the afternoon.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—On Monday, June 25th, at 7.30 p.m., the Honorary Fellowship of the College will be conferred on Sir Harold Stiles, Regius Professor of Clinical Surgery in the University of Edinburgh. The Charter Day dinner will be held in the College Hall immediately after the ceremony.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXV.—THE PROPHYLACTIC TREATMENT OF PUERPERAL SEPSIS.

CERTAIN facts as to how puerperal sepsis arises are well known: (1) There are undoubted cases of auto-infection arising from a pre-existing focus of sepsis in the mother herself, which is roused to renewed activity immediately after delivery, when the puerperal woman apparently passes from a condition of comparative immunity to one of special susceptibility. (2) It may, however, and probably most often does, arise by introduction of pathogenic germs by the accoucheur, either through error in the technique of sterilisation of his own person or by introduction of germs from the vulva, perineum, or anus of the mother when making examinations. (3) Infection may be introduced into the genital canal of the puerperal woman, especially when lacerations are present, through carelessness in nursing, through infection by the hands of the patient herself, or by intercourse taking place in the early days of the puerperium.

Such "accidents" will only be abolished by the adoption in midwifery of routine methods which are easily available, can be used quickly and safely by a busy practitioner whose days are full of other responsibilities besides midwifery, and become a habit which it is easier to follow than to break.

Auto-infection.

Auto-infection can only be prevented by careful examination during pregnancy, with treatment of septic conditions, such as:—

(a) *Oral sepsis* has very real import for midwifery. Even alveolar abscess and infection of sinuses are occasionally found in pregnant women who make no complaint till questioned; pyorrhœa and septic throats are not uncommon. Dental clinics for expectant mothers should help the practitioner to secure clean dental conditions for poor patients, and private dentists are available for others. The superstition that dental interference should be postponed until after delivery must be fought.

(b) *Staphylococcal infections*, such as whitlows, sores on the head or elsewhere, boils, &c., if present, should be dealt with before labour sets in. When generalised sepsis, such as recurring boils, is present, injections of collosol manganese into the muscles of the buttock give good results.

(c) *Vaginal discharge* is important, and must not be overlooked; it usually comes from a chronic endocervicitis, which may be due to the gonococcus or to other organisms. In any case, the cervix should be rendered aseptic during pregnancy, for a discharge may not only infect the child's eyes at birth if gonorrhœal in origin, but is a possible source of infection of the placental site after delivery. When vaginal discharge is present the appendages should also be examined, for chronic salpingo-oöphoritis still further increases the risk of puerperal fever. Incidentally, when chronic tubal trouble is lighted up after delivery the rise in temperature is more likely to occur seven than three days after delivery.

Allied to that of auto-infection is the question of the general resistance of the patient; lowered resistance may be present without obvious sepsis, and should none the less be treated. Healthy women feel a greater sense of vitality during pregnancy than at other times. If pregnancy seems a burden to a woman her general health and nutrition need attention before the strain of labour comes.

Sepsis during Labour.

Ante-natal Examination.—The avoidance of sepsis introduced at the time of labour is to some extent dependent on efficient examination during pregnancy, in order to ascertain if the size of pelvis and child

are normal in relation to each other. Attempts are sometimes made to deliver a large child through a small pelvis, involving a severe and damaging operative delivery, when such risks might have been avoided by induction of labour a few weeks earlier. Labour in which manipulative interference and damage to tissues play a part must obviously be more often associated with the introduction of pathogenic bacteria than normal delivery, and with greater ante-natal care such labours should become more rare.

Assistance Available during Labour.—This has a practical influence on aseptic results. Practitioners should work in coöperation with a trained nurse-midwife and an anaesthetist. The nurse must be specially trained in abdominal examination and diagnosis, and in methods of strict asepsis. *The anaesthetist should be available for the whole of the second stage.* The nurse will prepare the patient at the beginning of labour, and if there is any doubt whether the case is normal or if the patient is a primipara the practitioner should be summoned; many complications are avoided by seeing a primipara at the beginning of labour, and at least ascertaining by abdominal examination that the child's head has descended into the pelvis. Preparation by the nurse will include the emptying of the lower bowel by enemata, after which the posterior part of the vulva and round the anus should be shaved. The vaginal orifice and perineum and surrounding parts of the skin should be thoroughly washed with warm water and ether soap, and the whole area is painted when dry with iodine solution, after which a sterile sanitary pad or towel should be applied. In primiparae the repeated application to the perineum during labour of warm sterile pads soaked in lysol (1 in 320) will serve the double purpose of relaxing the perineum and disinfecting the surface.

The Second Stage.—When the second stage begins, which the midwife will recognise by the rupture of membranes and alteration in the character of the pains, the patient should be relieved by chloroform, a few drops being given on an open gauze mask just before each pain. The time may be recognised either by the quickening of the pulse or the gradual hardening of the uterus, and even a few drops given immediately either sign appears relieve the distressing character of the pain. The patient can still use her voluntary muscles to bear down during a pain, and can sleep quietly between the pains, with lessened nervous tension and exhaustion. The patient should be able to talk coherently when awake, until the head is on the perineum, when she is gradually allowed to become more unconscious. If not needed before, the accoucheur will be summoned when delivery approaches. The patient should be anaesthetised to full surgical anaesthesia at the moment of delivery of the head, after which no more anaesthetic need be given unless stitches are required. Anaesthetics during labour not only relieve the patient from immediate pain and subsequent exhaustion, but ensures a relaxation of the muscles of the pelvic floor during the passage of the head; thus lacerations, which predispose to sepsis, may be avoided, and also intrinsic damage to the muscles and fasciae with subsequent prolapse of organs.

Sterilisation of Outfit.—A quick effective method for ensuring sterile conditions is of great importance to the busy practitioner. A tin of sterilised necessities is essential. It should contain gown, head-piece, and gloves; a square of gamgee tissue to go under the patient as she lies in the left lateral position; a square sheet slit up the middle half way; towels, swabs, a roll of gauze, sanitary pads, binder, thread and dressings for the cord. The slit sheet (A) is easily prepared and is used to cover the patient and keep the area of operations aseptic. The top of the slit lies at the anal cleft, the upper part of the divided portion covers the right thigh and the lower half passes over the median surface of the left thigh. The undivided part of the sheet covers the body of the patient and her coverings and enables a sterile hand to pass over it to the abdomen without fear of contamination. A sterile towel below completes the aseptic area.

The easy aseptic adjustment of gloves is most important. For sterilisation each pair should be placed in a special linen case (B) after being powdered inside and out and the cuff folded back so that only the inside of the glove is touched when they are put on. A towel to dry the hands before putting on the gloves should be placed between each glove case. The linen case has two pockets, one for each glove, with a small pocket for a bag of powder for the fingers. The case can be opened on a table, the fingers powdered and each glove drawn on in a few

A, square sheet slit up to middle; B, linen case, with pockets for gloves; C, small pocket for powder.

seconds. After washing the accoucheur can slip on gown, head-piece, and gloves in a minute or two; the area of the patient with which he comes in contact has already been rendered aseptic by the nurse. After the birth of the child careful examination of the perineum and inner aspect of the vaginal orifice will enable the accoucheur to recognise and repair any tears and hence to leave no open wound in a neighbourhood very liable to sepsis.

The Third Stage.—The conduct of this stage should not be hurried. If after the child is born the uterus is allowed to rest without undue anxious stimulation, the placenta is more likely to be expelled naturally by an effective pain. Manual removal of a so-called adherent placenta should be avoided unless dangerous hæmorrhage renders it essential. It involves a greater risk of puerperal sepsis than any other manipulation in midwifery.

The Puerperium.—The prevention of sepsis in the early days of the puerperium depends on the nurse. Irrigation of the perineum, which is dried by sterile gauze, is better than swabbing. The aseptic care of the breasts requires a sterilised box such as a good-sized cigarette box for each patient. It should contain a pile of gauze squares and cubes of wool packed. If given boric lotion the patient can herself swab the nipples with wool and dry them with gauze before and after each feed. Breasts thus cared for will not develop septic conditions. The patient must be guarded during the first week from the introduction of infections through visitors.

Sundry Points.—In every district, if aseptic midwifery is to be carried on, a central sterilising station, public or private, should be available for the supply of sterilised midwifery tins, dressing tins, with such other requirements—e.g., for the breasts—as practitioners may need. The services of an anaesthetist for midwifery ought not to be considered a luxury but a necessity, to be paid by public funds if necessary.

The conduct of normal labour only has here been discussed. It is desirable that operative midwifery should be conducted in a properly equipped labour ward or theatre. Practically, however, many operative procedures have to be done in the bedroom. All the more essential then is the provision of an ample supply of sterile towels, &c., and extra gloves. Instruments after boiling should either remain in the steriliser, or be placed on a dish previously rinsed in strong lysol and covered by a sterile towel. Before any delivery vaginal retractors, large-toothed vulsellæ, a few Spencer Wells forceps, dissecting forceps, needles, silkworm gut and needle holders, and also sterile catgut should be boiled ready for use though they may not be required.

FLORENCE E. BARRETT, C.B.E., M.D., M.S.Lond.,
Consulting Obstetric and Gynaecological Surgeon,
Royal Free Hospital.

Special Articles.

BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING AT PORTSMOUTH.

PROVISIONAL PROGRAMME.

THE ninety-first annual meeting of the British Medical Association will be held at Portsmouth from July 24th-27th, under the presidency of Mr. Charles P. Childe. The Association last met at Portsmouth in 1899, under the presidency of the late Dr. J. Ward Cousins. The annual meeting will be preceded by the annual meeting of the Representative Body, which will be opened at 10 A.M. on Friday, July 20th, with Dr. R. Wallace Henry in the chair. The statutory annual general meeting will be held at 2 P.M. on Tuesday, July 24th. The President will deliver his address on that evening, and the adjourned general meeting will be held at 7.45 P.M. The annual dinner of the Association will take place in the Town Hall on Thursday, July 26th, at 7.30 P.M. The annual exhibition of surgical appliances, food, drugs, and books will be open from July 25th-27th.

The scientific part of the meeting will divide, as usual, into a number of sections meeting from 9.45 A.M. to 12.45 P.M. for papers and discussions; laboratory and clinical demonstrations in connexion with the work of the sections will be given in the afternoons.

The following sections each meet on three days—Wednesday, Thursday, and Friday, July 25th, 26th, and 27th.

Medicine.

President: Sir Thomas J. Horder. Vice-Presidents: Drs. George A. Allan, J. J. Perkins, John Phillips, C. F. Routh, J. Odery Symes. Hon. Secretaries: Dr. R. A. Dove, "Chesterfield," Elm Grove, Southsea; Dr. Geoffrey Evans, 23, Park-square, London, N.W. 1.

Provisional Programme.—July 25th.—Discussion: Diabetes. To be opened by Sir Thomas Horder, followed by Drs. P. J. Cammidge, George Graham, J. A. Nixon, and John K. Rennie. Dr. F. G. Banting (Toronto), the discoverer of insulin, will also take part in the debate.

July 26th.—Discussion: The *Ætiology* and Treatment of Heart Disease in Early Life, with special view to the prevention of Chronic Cardiac Insufficiency. To be opened by Dr. Reginald Miller, followed by Drs. G. A. Allan, J. G. Emanuel, T. F. Cotton, Carey Coombs, Wilfrid Attlee, and M. O. Raven.

July 27th.—Discussion: Chronic Bronchitis. To be opened by Dr. J. J. Perkins, followed by Drs. J. O. Symes, E. Hyla Greves, M. G. Foster, A. C. Inman, E. L. Collis, and Mr. G. Seccombe Hett.

Surgery.

President: Sir Henry M. W. Gray. Vice-Presidents: Mr. Douglas Drew, Sir T. Crisp English, Mr. T. A. Munro Forde, Mr. John Patrick, Mr. Percy Sargent. Hon. Secretaries: Mr. Harold Burrows, The Cams, Grove-road, Southsea; Mr. B. C. Maybury, 42, Wimpole-street, W. 1.

Provisional Programme.—July 25th (10 A.M.).—Discussion: The Treatment of Obstruction of the Colon. To be opened by Mr. Arthur H. Burgess, followed by Messrs. Seymour G. Barling, Arthur B. Mitchell, Herbert W. Carson, John P. Lockhart-Mummery, and Charles A. Pannett. Discussion (12 noon): Are the Results of the Operative Treatment of Malignant Disease Improving? To be introduced by Mr. H. J. Paterson.

July 26th.—Discussion: The Treatment of Acute Primary Infections of the Hand (including sequelæ). To be opened by Mr. David P. D. Wilkie, followed by Messrs. C. Max Page, F. D. Saner, Gerald T. Mullally, and R. M. Handfield-Jones. Discussion (12 noon): Ventriculography. To be introduced by Mr. A. A. McConnell.

July 27th.—Discussion: Anæsthetics from the Surgeon's Point of View. To be opened by Mr. Wilfred Trotter, followed by Sir William de Courcy Wheeler and Drs. A. L. Flemming, J. Blomfield, and A. E. Boyd.

Obstetrics and Gynaecology.

President: Mr. Victor Bonney. Vice-Presidents: Prof. W. Blair Bell, Dr. James Hendry, Dr. Louisa Martindale, Dr. A. Bosworth Wright. Hon. Secretaries: Dr. Gertrude Dearnley, 27, Seymour House, Compton-street, London, W.C. 1; Dr. E. F. S. Green, 8, Victoria-road, Southsea.

Provisional Programme.—July 25th.—Discussion: Treatment of Acute Salpingitis. To be opened by Mr. Aleck Bourne, followed by Profs. W. Blair Bell and C. G. Lowry, Mr. L. Phillips, Drs. C. Oldfield, J. Campbell, F. Edge, Miss F. Ivens, Mr. Beckwith Whitehouse, Drs. Eardley Holland and S. Forsdike, Mr. L. Rivett and Mr. Victor Bonney.

July 26th.—Discussion: The Use and Abuse of Forceps. To be opened by Mr. Comyns Berkeley, followed by Profs. C. G. Lowry, J. A. Kynoch, and R. G. McKerron, Drs. J. Campbell, F. Edge, and C. E. Purslow, Miss F. Ivens, Dr. S. Forsdike, Mr. L. Rivett, Drs. D. McAskie, R. K. Ford, and Mr. Victor Bonney. At 3 P.M. Lieut.-Colonel A. Buchanan, I.M.S., will give a demonstration of midwifery models.

July 27th.—Papers: Prof. W. Blair Bell: Modern Views on Dysmenorrhœa; Prof. C. G. Lowry: Three Cases of Chorion-epithelioma, and One Case of Tuberculosis of the Cervix; Mr. Beckwith Whitehouse with Dr. Henry Featherstone: Certain Observations on the Innervation of the Uterus; Dr. S. Forsdike: Treatment of Uncontrollable Uterine Hæmorrhage by Radium; Mr. Lane Roberts: Syphilis in its Relation to Obstetrics; and Dr. W. R. MacKenzie: Röntgenographic Pelvimetry.

Pathology and Bacteriology.

President: Dr. Hugh Maclean. Vice-Presidents: Prof. Frederick Hobday, Dr. A. F. Bernard Shaw, Prof. G. Haswell Wilson. Hon. Secretaries: Dr. J. A. D. Radcliffe, 41, Clarendon-road, Southsea; Dr. R. L. Mackenzie Wallis, 105, Harley-street, London, W. 1.

Provisional Programme.—July 25th.—Discussion: Diseases of the Stomach, particularly with reference to Modern Methods of Investigation. To be opened by Dr. Charles Bolton.

July 26th.—The Value of Serological Tests in Diagnosis. To be opened by Prof. H. R. Dean.

July 27th.—The Part Played by Fungi in Disease. To be opened by Dr. A. Castellani.

The officers of the Section will be glad of the loan of X ray negatives or prints for exhibition in the Museum. Offers should be addressed to Dr. M. Aston Key, 14, Clarendon-road, Southsea, Portsmouth.

Neurology and Psychological Medicine.

President: Dr. Henry Devine. Vice-Presidents: Drs. D. K. Henderson, C. M. Hinds Howell, George Riddoch, E. J. Davis Taylor. Hon. Secretaries: Dr. J. L. Jackson, Knowle Mental Hospital, Fareham, Hants; Dr. C. P. Symonds, 74, Wimpole-street, London, W. 1.

Provisional Programme.—July 25th.—Discussion: The Nervous Child. To be opened by Dr. H. C. Cameron.

July 26th.—Discussion: The Sequelæ of Encephalitis Lethargica. To be opened by Dr. E. F. Buzzard. In the afternoon Dr. C. Da Fano will give a demonstration on Epidemic and Herpetic Encephalitis.

July 27th.—Discussion: The Prognosis in Psychosis occurring during Adolescence. To be opened by Dr. D. K. Henderson.

The following sections will each meet on two days:—

Ophthalmology.

President: Sir John H. Parsons. Vice-Presidents: Dr. W. S. Inman, Mr. Ransom Pickard. Hon. Secretaries: Mr. M. W. B. Oliver, 128, Harley-street, London, W. 1; Dr. J. A. Valentine, South View Lodge, 53, Kent-road, Southsea.

Provisional Programme.—July 26th.—Discussion: The Clinical Significance of Scotometry. To be opened by Mr. A. H. H. Sinclair.

July 27th.—Discussion: Ophthalmology in its Relation to the Navy, Army, and Air Force. Air Commodore D. Munro will speak, and other officers of the R.A.F. and from the Navy and Army will take part.

Public Health.

President: Dr. A. Mearns Fraser. Vice-Presidents: Dr. W. J. Howarth, Dr. L. E. W. Stephens, Prof. F. E. Wynne. Hon. Secretaries: Dr. W. H. Lamplough, Bredon, Alverstoke; Dr. E. Lewys-Lloyd, Gothic House, Towyn, Merionethshire.

July 26th.—Discussion: What Factors have contributed towards the Recent Decrease of Infantile Mortality, and are such Factors likely to be Permanent or Temporary? To be opened by Dr. James Wheatley.

Paper: Dr. H. Scurfield: The Value of Watercress as a Food, and Suggestions for its Extended Use.

July 27th.—Discussion: The Effect on Health of Sewer Air and Drain Air. To be opened by Prof. F. E. Wynne.

Paper: Dr. E. B. Hazleton: A Predisposing Cause of Tuberculosis and its Prevention.

Diseases of Children.

President: Dr. Edmund Cautley. Vice-Presidents: Drs. Catherine Chisholm, William P. McEldowney, Eric Pritchard. Hon. Secretaries: Dr. E. A. Cockayne, 33, Weymouth-street

London, W. 1; Dr. R. Hamer Hodges, 93, Victoria-road, N., Southsea.

Provisional Programme.—July 26th.—Discussion: Acidosis and Alkalosis in Children. To be opened by Dr. P. J. Cammidge.

July 27th.—Discussion: Summer Diarrhoea. To be opened by Dr. David Nabarro.

Paper: Dr. H. T. Ashby: After-effects of Tuberculosis of Abdomen in Children.

Laryngology and Otolology.

President: Dr. E. B. Waggett. Vice-Presidents: Messrs. Somerville Hastings, A. J. M. Wright. Hon. Secretaries: Dr. G. H. Ross, 28, Kent-road, Southsea; Mr. H. G. Bedford Russell, 86, Harley-street, London, W. 1.

This Section meets on July 26th and 27th.

Provisional Programme.—(a) Laryngology.—Discussion: Spasm of Larynx. To be opened by Sir StClair Thomson. (b) Otolology.—Discussion: Non-suppurative Conditions of the Labyrinth. To be opened by Mr. Sydney R. Scott.

Radiology and Electrolology.

President: Dr. S. Gilbert Scott. Vice-Presidents: Prof. Sidney Russ, Dr. W. J. Turrell. Hon. Secretaries: Dr. E. Beverley Bird, 15, Clarence Parade, Southsea; Dr. G. T. Loughborough, 9, Bentinck-street, London, W. 1.

Provisional Programme.—July 25th.—Discussion: The X Ray Examination of the Urinary Tract. To be opened by Dr. R. W. A. Salmond. Paper: Pyelography, by Dr. R. Ogier Ward.

July 26th.—Discussion: Medical Diathermy. To be opened by Dr. E. P. Cumberbatch. Supplementary paper: Dr. C. A. Robinson.

There will be an exhibition of X ray negatives and prints of the urinary tract. Prints or negatives (up to the number of ten for any name or hospital) should be sent to Dr. E. Beverley Bird, 15, Clarence Parade, Southsea, before July 10th.

Naval and Military Hygiene.

President: Surgeon Rear-Admiral Sir Percy W. Bassett-Smith. Vice-Presidents: Surgeon Captain R. St. G. S. Bond, Air Commodore David Munro, Sir Leonard Rogers, Lieut.-Colonel N. J. Crawford Rutherford. Hon. Secretaries: Surgeon Commander K. Digby Bell, R.N., Royal Naval School of Physical Training, Portsmouth; Surgeon Commander D. H. C. Given, R.N., Commander-in-Chief's Office, Portsmouth; Captain W. L. E. Fretz, R.A.M.C., Alexander Military Hospital, Cosham, Hants; Wing Commander H. E. Whittingham, R.A.F., Central Laboratory, Avenue House, East End-road, Finchley, N. 3.

Provisional Programme.—July 25th (10 A.M.).—Papers: Group Captain M. W. Flack: Some Considerations in the Estimation of Physical Efficiency; Lieut.-Colonel C. R. Sylvester-Bradley: Some Aspects of Normality, with special reference to the Selection of Recruits; Surgeon Commander K. Digby Bell: Some of the Points Embodied in the Curriculum of a Student of Physical Training.—(12 noon): Wing Commander H. E. Whittingham and Flight Lieut. A. F. Rook: The Aetiology of Phlebotomus Fever.—(2.30 P.M.): Visit to Royal Naval School of Physical Training, where a demonstration and discussion will take place.

July 26th (10 A.M.).—Papers: Major M. Sinclair: Recent Changes in Fracture Treatment; Surgeon Captain D. W. Hewitt: Some General Remarks on Naval Surgery; Major H. Graeme Anderson: Aeroplane Accidents.—(2.30 P.M.): Demonstration by Major M. Sinclair of special appliances for treatment of fractures. Visit to Royal Naval Hospital, Haslar.

Tuberculosis.

President: Sir Henry J. Gauvain. Vice-Presidents: Drs. Robert Robertson, Jane Walker, R. A. Young. Hon. Secretaries: Dr. W. Young Woodburn, 75, Festing-road, Southsea; Dr. J. Browning Alexander, 143, Harley-street, London, W. 1.

Provisional Programme.—July 25th.—Discussions: (1) The Artificial Light Treatment of Lupus and other Forms of Tuberculosis. To be opened by Prof. Reyn (Copenhagen), followed by Dr. J. H. Sequeira. (2) The Present Position of the Surgical Treatment of Pulmonary Tuberculosis. To be opened by Dr. Gravesen (Vejlefjord Sanatorium).

July 26th.—Discussion: The Social Aspects of Tuberculosis, with special reference to Infectivity. To be opened by Dr. Jane Walker, followed by Dr. H. Batty Shaw, Prof. S. Lyle Cummins, Drs. F. N. K. Menzies, G. Brookes Dixon, and John E. Chapman.

The following sections will each meet on one day.

Medical Sociology.

President: Dr. H. B. Brackenbury. Vice-Presidents: Drs. Alexander Forbes, L. A. Parry, Sir Leslie Scott. Hon. Secretaries: Dr. Arnold Lyndon, Grayshott, Hindhead, Surrey; Dr. A. H. S. Roberts, 428, Commercial-road, Portsmouth.

Provisional Programme.—July 27th.—Discussion: Mental Deficiency in its Social Aspects—(a) education, (b) segregation, (c) sterilisation. Dr. William Potts and Mrs. Helen Pinsent (Board of Control) will open the discussion. Drs. Henry Devine, C. Macfie Campbell (U.S.A.), Joseph F. E. Prideaux, Miss Evelyn Fox (Hon. Secretary, Central Association for Mental Welfare). Drs. W. Norwood East, and R. A. Gibbons will speak under the various heads.

Apparatus for mental tests and an exhibit of work done by mental deficient will be shown in the Pathological Museum. A film illustrating the education of mentally deficient children will be shown by Miss Evelyn Fox in the exhibition on Friday afternoon.

Orthopaedics.

President: Mr. T. H. Openshaw. Vice-Presidents: Messrs. A. S. Blundell Bankart, James Russell. Hon. Secretaries: Mr. W. Martin, 43, Clarendon-road, Southsea; Mr. P. J. Verrall, 116, Park-street, London, W. 1.

Provisional Programme.—July 27th (10 A.M.).—Discussion: The Operative Treatment of Osteo-arthritis. To be opened by Mr. R. C. Elmslie, followed by Messrs. Harry Platt, P. Jenner Verrall, McCrae Aitken, and others. 11.45 A.M.: Papers: Mr. E. Laming Evans: Acute Rachitis in Late Childhood and Adolescence; Dr. Robert Milne: The Prognosis of Legg's Disease of the Hip; Mr. P. Bernard Roth: The Treatment of Fractures of the Lower End of the Humerus; Mr. Naughton Dunn: Congenital Talipes Equinovarus, its Prognosis and Treatment; Mr. T. H. Openshaw: Some Deformities of the Os Calcis.

Venereal Diseases.

President: Sir Archdall Reid. Vice-Presidents: Messrs. David Lees, Kenneth M. Walker. Hon. Secretaries: Dr. Archibald Campbell, 12, Prudential Buildings, Portsmouth; Dr. W. R. Snodgrass, 43, Ashton-terrace, Hillhead, Glasgow.

Provisional Programme.—July 27th.—Discussion: Prevention and Treatment of Chronic Gonococcal Prostatitis and Vesiculitis. To be opened by Mr. Kenneth M. Walker and Dr. David Watson.

Anaesthetics.

President: Dr. W. J. Essery. Vice-Presidents: Drs. H. E. G. Boyle, W. Carling, C. H. Mott. Hon. Secretaries: Dr. R. H. Emmett, The Corner, London-road, Portsmouth; Dr. H. R. Phillips, 2, Cumberland Mansions, Bryanston-square, W. 1.

Provisional Programme.—July 26th.—Papers: Dr. Harold Sington: Anaesthesia for Children; Dr. Arthur L. Flemming: Fatalities from Anaesthetics; Dr. H. E. G. Boyle: Paper and Demonstrations of Apparatus for Administration of Gas, C.E., and Oxygen.

The hon. local general secretary is Mr. C. A. Scott Ridout, St. Elmo, Clarendon-road, Southsea; the assistant hon. general secretary is Dr. E. J. Davis Taylor, 20, Clarence-parade, Southsea.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Amendment of the Sick Club Act.

THE law relating to sick-clubs has recently been amended. The Government had intended a fundamental alteration of insurance laws, but this would have entailed great loss of time, and the financial position of the clubs necessitated immediate assistance. An Act was therefore passed to obviate the more pressing difficulties. The Minister of Labour is thereby empowered to fix the maximum income, receipt of which compels the receiver to belong to a sick-club, but workmen, apprentices, and domestic servants will continue to be compulsory members apart from their rate of wages. At present the maximum income is fixed at M.4,880,000 a year. Members who receive more than this amount must continue to pay contributions for three months. Sick-clubs attached to individual factories and trades are to be licensed only when they contain more than 1000 members, otherwise they are compelled to amalgamate with a local general sick-club. The new law provides that the bottles for medicine given to club patients in the pharmacies belong not to the patient but to the club, and that clubs are authorised to issue regulations to safeguard their property. The General sick-club of Berlin, the largest in Germany, has therefore ordered that every patient receiving medicine has to give security to the chemist to the value of the bottle.

Problem of Decreased Birth-rate.

In a recent lecture delivered before the Berlin Medical Society, Dr. Hamburger stated that the general rate of mortality in Germany had apparently improved since the war, not because of any general improvement of health (the latter having, as a matter of fact, become much worse) but because of a decreased birth-rate. In 1920 the surplus of births over deaths was 10.3 per cent., and in 1921 11.4 per cent., but in the first quarter of 1922 the figure sank to 6.9 per cent. The last quarter of 1920 saw the greatest number of weddings of recent years, so that a record number of births was expected in the third quarter of 1921; but the actual figure was much lower than that customary before the war. Thus the greater part of the population must be presumed to have used means to prevent births. Infant mortality has decreased among children born in wedlock, whilst among illegitimate children it has remained stationary. Obviously a smaller number of children enables the mothers to take more care of each individual child. Infant mortality was at one time higher in Germany than in any other civilised country of Europe, owing, it was commonly stated, to the habit—common among the poorer classes—of overfeeding infants, which often caused severe gastro-intestinal trouble, with choleraic diarrhoea, leading to death. The desire to avoid parenthood has stimulated illegal induction of abortion, which is often followed by puerperal fever. Dr. Hamburger stated that about 5000 women annually die from puerperal fever in Germany, and that about 15,000 more, after having that disease, are left with sexual organs so injured that they are unable to give birth to a child. In the discussion which followed the reading of Dr. Hamburger's paper, Prof. Bumm stated that the majority of cases of puerperal fever were due to illegal abortion. In the gynaecological clinic at the University of Berlin, he said, the number of abortions exceeded that of births. Formerly only unmarried women resorted to the practice, but now about 80 per cent. of miscarriages occur in married women, the reason being the general financial distress of the population and lack of room for more children. The procuring of abortion, apart from medical necessity, was now a crime, but it had been proposed—and Parliament might shortly consider the proposal—that artificial abortion, if performed at the mother's request, by a qualified medical man, should be permitted. The practice of abortion had already spread so widely that it would scarcely be possible to abolish it. Dr. Hirsch spoke of the advantages of rearing a smaller number of healthier children in preference to a larger number, including many unfit to some degree. In his reply, Dr. Hamburger stated that the number of births had considerably decreased during the war in all great cities—e.g., Paris, Moscow, and Berlin, but that everywhere the number had risen afterwards—least in Berlin, and most in Moscow, although artificial abortion was not legally prohibited in Russia. It could thus be performed by qualified medical men, a fact which would greatly reduce the number of deaths from puerperal fever. The only remedy against the decrease of births would be an improvement of the financial condition of Germany.

Organisation of the Universities.

The Secretary of State for Education lately stated before the Prussian Parliament that the organisation of the personnel of the universities, and especially of the Medical Faculties, is to be simplified. Hitherto it has been composed of the following categories: (1) The ordinary professors, having a seat in the faculty, and a vote in elections to the offices of dean of the faculty and rector of the university; (2) extraordinary professors, with a commission to teach certain branches of medicine, who receive a salary apart from lecture fees; (3) extraordinary professors not having a commission, and receiving lecture fees from the students but no salary from the Government

—i.e., the "privat-docents" with no other privilege than that of delivering lectures, although some had the title of professor conferred upon them by the Minister of Education. Henceforth there will be (1) ordinary professors; (2) extraordinary professors, all salaried, and all possessing the right to vote in the elections of dean and rector, these offices remaining open only to ordinary professors; (3) privat-docents, having the right of sending representatives to meetings of the faculty, with a consultative vote. The title of professor will henceforth be reserved to the appointed members of the faculties. Towards the end of the imperial régime the title of "professor" had lost much of its former value in the scientific world, as it was commonly conferred by the Government upon privat-docents, assistants of university clinics and institutes, and even hospital physicians and specialists having no connexion with the universities. The termination of this abuse—as the Republican constitution forbids conferment of a title unless the bearer holds an office—will give a great advantage to the university professors, and will place other medical men under a corresponding disadvantage, as the public will continue to believe that a "professor" must be cleverer than a medical man without that title.

Training of Nurses for Children.

New regulations on the training and examination of nurses for children have been issued by the Minister of Public Health. The training will extend over two years in a children's hospital; only women of at least 20 years of age, possessing a certificate of health and good conduct, will be admitted. Qualified midwives desiring to obtain the certificate will be allowed to undergo a shorter training. The examining board will be composed of a medical officer and two specialists in children's diseases. The examination includes the elements of anatomy and physiology of the human body, the care of healthy and of sick infants, the preparation of food, and the diseases of children, with prophylaxis of infectious diseases, disinfection, and reports to medical attendants. Special stress is laid on the principles of feeding of infants, and on the care of diseases of the gastro-intestinal canal. The candidate must nurse a couple of children for some days to the satisfaction of the examining board, and must make a full report on the cases. Candidates who have passed the examination receive a certificate by which they are allowed to call themselves "qualified children's nurses"; a qualification which may be withdrawn for immoral conduct or unprofessional behaviour.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Correlations Between Syphilis of the Aorta and Syphilis of the Nervous System.

Dr. Frisch, in a recent report to the Medical Society of Vienna on the results of investigations into the combination of syphilis of the aorta and syphilis of the nervous system, stated that he had examined 115 manifest cases of the latter condition, of which 39 per cent. showed distinct symptoms of syphilitic aortitis. In general paralysis of the insane he found 29 per cent., in tabes dorsalis 48 per cent., and in cerebro-spinal syphilis 35 per cent. of cases with aortic changes. It is peculiar that of the whole series only 2 patients complained of subjective symptoms due to this condition; in all other patients the aortitis gave no discomfort. Dr. Frisch thought that this fact was due to a disturbance of the sensibility of the viscera, and that syphilitic aortitis was much less troublesome in itself than the arterio-sclerotic form. He suggested that the chemotropism of the spirochæte was influenced by the cellular make-up of the individual attacked by the disease, so that ectodermal syphilis of the nerves was opposed to mesodermal syphilis of the aorta.

Statistical Data Concerning Cancer.

In the pathological institutes of Vienna exact statistics referring to cancer incidence are being prepared. During the past 10 years cancer was noted as present in 8 per cent. of post-mortems observed there, the ratio of frequency being as follows: intestinal canal, stomach, 30 per cent.; colon, 15 per cent.; oesophagus, 6.5 per cent.; ovaries and uterus, over 15 per cent.; gall-bladder, 6 per cent.; mammae, 5.5 per cent.; respiratory system, 3.5 per cent.; other organs were less frequently affected. Of all neoplasms, over 94 per cent. were cancerous; sarcomata and mixed tumours were not frequent. The cancer incidence has been fairly stable for a number of years, whilst tuberculosis, for instance, shows rhythmic increase and decrease. In recent times, following the increase of early diagnosis and early treatment, the number of unrecognised cases of cancer has been markedly lower, but over 8 per cent. of the cases are still unsuspected by their medical attendants or are at least termed "intercurrent," another disease being regarded as the underlying cause of death. There is apparently a slight progressive increase in the incidence of cancer of the breast and sexual organs in females.

A Secession from the Medical Organisation.

Nearly 100 per cent. of the medical men in Vienna, practitioners and other doctors alike, have hitherto been united in a solid body known as the W.O. (Wirtschaftliche Organisation, or economic union) of Vienna. By strict adherence to a trade-union system, coupled with liberal recognition of the needs of each group in the union, a large number of professional grievances have been abated and numerous advantages have been obtained for members. One of the most notable achievements in this connexion was the securing of the free choice of doctor, to which the Krankenkassen (sick-clubs) of the State railways, of the Municipality of Vienna, and of the Civil Service had to agree, a comparatively satisfactory rate of payment and employment being thus obtained for the profession in general. Now, however, a serious upheaval has occurred and the large group of non-practising hospital assistants and juniors, numbering some 560, have resolved to resign their membership; this break in the solidity of the W.O. is seriously handicapping its work. The trouble arose over a decision of the board of the W.O. to the effect that hospital doctors with full pay should not practise privately, and that no married house physician or house surgeon should be appointed. As the W.O. is chiefly concerned with the economic welfare of its members and private practice is the paramount object of every doctor, this decision is in the nature of protection of the private practitioner from the competition of men not handicapped by household expenses, who are at the same time able to command the use of hospital appliances with no cost to themselves. The hospital doctors, in taking such drastic action, have apparently overlooked the fact that the junior of to-day is the practitioner of to-morrow. Further consideration has already given rise to a counter movement in the seceding section, aimed at re-entry into the union. In order to facilitate this movement a new governing body is to be elected by a fresh system of voting, which will ensure to every group of doctors (i.e., general practitioners, specialists, public health officers, panel doctors, hospital staffs, lecturers, research workers, &c.) a representative on the board. Each section will delegate its own representative and an attempt will be made to reconcile the demands of hospital doctors with general professional needs. Other reasons for secession have also been advanced by several groups of members, chiefly relating to politics, religion, or nationality, but the board rightly insisted on its strictly economic duties, refusing to consider any standpoint other than that of the man in practice, who cannot afford to select his patients according to creed or political convictions.

Anti-Rabies Campaign.

At a recent meeting of the Medical Society Prof. Schnürer read a paper on methods of combating the spread of rabies amongst dogs; fully 93 per cent. of all cases of hydrophobia are due to injuries by infected dogs. Towards the end of the war, and since that time, there has been, apparently throughout Europe, a distinct increase of cases amongst dogs. In Austria during 1921, 228 diseased dogs were reported; this figure rose to 581 in 1922. The rise was due not only to a relaxation of previously strict rules concerning household animals on the Continent generally, but also to an actual increase in the number of dogs. In Vienna, for instance, there were in 1919 about 37,000 dogs kept under licence; in 1922 the figure was 81,000—i.e., 1 dog to every 26 inhabitants. One of the chief means of prevention of rabies is to keep down the number of dogs by means of high taxation and licensing duties. In Vienna any dog found in the street without a special "dog medal" around his neck is liable to capture and destruction by the municipal dog-catcher, and no dog is allowed in the street without muzzle and chain. These two simple rules, if rigidly enforced, are sufficient to produce a rapid diminution of the number of cases of rabies. Compulsory notification of all cases of rabies, whether manifest or only suspect, is very important, and is enforced by law for all animals in Austria; every instance of a person being bitten by a dog, or of the killing of a suspected dog or cat, must also be reported to the authorities. Every suspected animal must be killed at once or kept under observation for four months in a special veterinary hospital. These measures have, of course, proved efficacious in nearly all civilised countries, and in some the disease has been eradicated, but every now and then a relaxation of vigilance, or an act of carelessness on the part of an owner, causes a fresh outbreak.

An Attack on Professional Secrecy.

Dr. Höples, Chief Public Prosecutor in Vienna, recently requested all medical corporations to inform their members that Austrian law requires every practitioner, hospital physician and surgeon, and midwife to inform the police of cases of attempted abortion coming to their professional knowledge. As numerous members of the medical profession had lately failed to comply with the requirements of the law, and as deliberate abortion is a criminal offence, he wished to remind doctors of their statutory duty in the matter. This request aroused unanimous opposition from medical men. The Vienna Aerztekammer (Medical Council) pointed out in a protest that it involved an attempt to abolish professional secrecy, which a doctor is compelled by law to maintain, being forbidden to disclose any knowledge obtained from his patients unless expressly questioned by order of a judge, and then the disclosures can be made only to the judge himself. If every case of suspected abortion was reported every case of hæmorrhage in a woman came under suspicion, and the situation would become impossible. A withdrawal of the order in question was demanded by the Council; a similar stand against its application was taken by the members of the Forensic Society of Vienna, by whom Dr. Höples was invited to open a discussion. The majority of the speakers—medical and legal—wished to leave such cases to the discretion of the doctor, permitting him to decide when a case of abortion was suspicious. During the discussion many who took part advocated a cancellation of the law making deliberate abortion a crime. Nowadays, it was argued, the right to curtail the family should rest with the parents; indiscriminate procreation of weak or sickly children did not tend to improve national health, whilst where there were children already an addition to the family might prove disastrous. Medical men strongly objected to assuming the rôle of police agents, a rôle which might be attributed to them if there was any weakening of professional confidence between themselves and their patients.

June 13th.

CZECHO-SLOVAKIA.

(FROM OUR OWN CORRESPONDENT.)

The Report on Vaccination.

THE law on compulsory vaccination, passed in 1919, has been very strictly enforced and has resulted in the eradication of small-pox in Czecho-Slovakia, but a considerable proportion of the population is strongly opposed to the measure. A number of protests made to Parliament have been handed over to the State Health Council for consideration. The opponents of compulsion ask for a State guarantee for cases where permanent damage or death may result from vaccination; many of the protests, of which the majority come from city councils, ask for the appointment of a joint committee of medical men and opponents of vaccination to study the question. The Health Council approved a resolution rejecting all suggestions contained in the protests, and recommended the organisation by the Public Health Service of a wide campaign of public health education, with special reference to vaccination and to the eradication of small-pox. The Council also opposed a suggested modification of the law on the lines of the present English law.

Social Insurance Scheme.

Dr. Lev Winter is giving a series of lectures in the Institute of Social Sciences, Prague, on the proposed scheme for social insurance (comprising sickness, old age, and invalidity insurance). This scheme was prepared by a special committee instituted for the purpose by the Ministry of Social Welfare, and Dr. Winter is among its most energetic supporters. The political parties upholding the present coalition régime have included social insurance in their working programme, and it is expected that the insurance scheme will be put into effect by Jan. 1st, 1924. The whole project is divided into two parts, one relating to insurance of labour and Civil Service officials, with provision for pensions, the other relating to insurance of small craftsmen and farmers—this latter part of the scheme being not yet completed. The two parts will come before Parliament separately; the Parliamentary Committee on Social Insurance will hold continuous sessions until the necessary work is finished. It was originally intended to include accident insurance also, but later it was decided to separate the latter, which has already existed for a long time, lest the machinery of insurance should become too complicated. The insurance of miners was also excluded, as this class of workers already have a system of their own. The projected scheme covers all wage-earners whose insurance is not provided for by any other means. The unit of organisation will be the political district (with an average population of 60,000 persons); in each district a bureau of social insurance will be created. In these bureaux will be concentrated all the existing small bureaux, which have been largely in the hands of political parties and were often badly managed. District insurance affairs will be controlled by delegates elected by the insured members; these delegates will elect an executive committee to direct the insurance bureau. The members of executive committees will elect and send 20 representatives of insured persons and 12 representatives of the employers to the Central Board of Social Insurance in Prague. Eight members of the Central Board and its chairman will be appointed by the President of the Republic. Payments to insured persons in case of sickness will be practically the same as under the present laws (approximately two-thirds of the member's wage). The projected law lays more emphasis on prevention of disease and on early treatment than on support of the sick member. The latter will be entitled to the invalidity and old age benefit after payment of 200 weekly contributions. Insured persons prevented by sickness from earning more than one-third of their previous wages will be entitled to invalidity benefit,

and those attaining the age of 65 years will receive the old age benefit; both these benefits will begin at 1000 crowns a year (150 Czecho-Slovak crowns equalling £1 sterling). The widows' benefit will be half, and the orphans' benefit one-third, of that sum. Payments will be made, half by the employer and half by the insured person, to the district insurance bureau. The insurance scheme will affect approximately 2,500,000 persons, two-thirds being males. It is anticipated that the scheme will unify sickness insurance and accelerate the development of preventive medicine in the Republic.

A Malaria Census.

The Ministry of Health have published facts relating to the spread of malaria in the Republic, based on the returns of a census especially organised for this purpose. The total number of malaria patients in Czecho-Slovakia was 26,664, of whom only 28 are women and 7 children; 16,345 soldiers contracted malaria during the war outside the territory of the Republic, and only 187 persons contracted the disease within the boundaries of the State. Although investigators detected anopheles in considerable numbers in some parts of the Republic, the facts seem to indicate that malaria was brought into the country by soldiers, and that it will die out automatically.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THREE COUNTY BOROUGHES.

THE following table gives the principal health statistics for three county boroughs, which have the point in common that they are comparatively free from industrial smoke. The death-rates from respiratory diseases, &c., however, are swollen in each case by the increased prevalence of influenza in 1922 when comparison is made with the previous year. The table also gives the principal health statistics of three of the smaller boroughs for 1922:—

Name of district.	Estimated population (mid-year).	Birth-rate.	Death-rates per 1000 of population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality.	Legit.	Maternal mort. in childbirth.
Brighton	135,000	16.9	14.6	1.3	1.8	3.3	61	143	3.5
Croydon	192,300	18.2	12.4	1.1	1.3	2.7	59	170	4.6
Reading	92,990	18.5	12.2	1.1	1.2	2.5	53	133	1.2
<i>Three Smaller Boroughs.</i>									
Ealing	67,890	16.2	11.0	0.7	1.3	2.2	43	255	2.7
Hove	44,110	13.1	14.2	0.8	—	—	39	148	3.4
Tunbridge Wells.	34,360	14.8	14.4	0.9	1.6	2.3	67	193	2.0

Brighton.

Dr. Duncan Forbes reports that during the year the Corporation have completed a desirable suburb at Moulsecoomb by the erection of 278 houses (making a total of 470), and that the first steps have been taken to deal with a small part of a slum area. Private enterprise has only contributed seven new houses during the year. The club-room for male consumptives continues to provide interest and enjoyment for patients under open-air conditions and coincidentally a certain amount of voluntary segregation. Since January, 1921, the midwives have practised the

routine administration of argyrol to the babies' eyes, and during these two years there has been a noteworthy drop in the notified cases of ophthalmia neonatorum. Of syphilis cases, 21 males and 12 females completed treatment during 1922, while 58 males and 26 females ceased to attend during treatment. With the exception of two consultants, no medical practitioners have made application for salvarsan substitutes during the year.

The school report states that the zinc ionisation treatment for discharging ears was introduced during the year and has given successful results. Details of typical cases are given. Of 58 cases treated, 42 were cured. A careful note is made of "tonsil and adenoid" cases before operation, and a note of the condition one year after operation is made for comparison. Of those children suffering from complications, the "year-after" examination showed that cures had been effected in 65.7 per cent. of the deafness, 62.7 per cent. of the otorrhoea, and 40 per cent. of the enuresis. Scabies in the schools is now down to pre-war proportions. The X ray treatment of ringworm continues to give good results. The new hair in most cases is very abundant, silky, and inclined to curl, a fact which gives "intense satisfaction to the parents." The system of examining ringworm contacts has been adopted. Of 181 contacts examined, 59 were found to be suffering, 18 of whom were under school age.

An industrial class for ineducable mentally defectives is run by the Guardianship Society, and it is hoped that a Ministry grant will soon be forthcoming for such classes. Rug-making, needlework, knitting, bead-threading, and drawing are taught. The secondary schools include boys and girls who have had dental treatment whilst at the elementary schools, and it is satisfactory to learn that 53 per cent. of the boys and 51 per cent. of the girls examined at the secondary schools during the year were found to have sound or perfect teeth.

Croydon.

Dr. K. Simpson, acting medical officer of health, reports that housing conditions are, on the whole, better, but that the improvement is slow. He recommends a more general enforcement of the by-laws for houses let in lodgings adopted in January, 1921. The 15 beds subsidised at St. Mary's Maternity Hostel are insufficient and at least 35 to 40 beds are needed. The normal births at the hostel are attended by pupil-midwives under supervision and the abnormal cases by a rota of practitioners. Of the 309 births occurring in the institution only 289 were live births, 10 being viable, and 10 non-viable stillbirths. Midwives attended 45 per cent. of the registered births in the borough, 1655 being live births and 52 stillbirths. Dr. Simpson advocates the provision of dental treatment for expectant mothers and a closer co-operation between the ante-natal and venereal disease clinics. Special weekly clinics for foster-children were instituted in 1921 and massage clinics are held for children suffering from various atrophies, rickets, debility, &c.

Additional tuberculosis visitors are needed to cope with the work of bringing up contacts for examination. During the latter part of the year the available accommodation at the special school for mental defectives proved insufficient, and Dr. Simpson thinks some other provision should be made for the lower-grade cases, who are, at present, a hindrance to the progress of the higher-grade child. A beginning has been made by the provision of a small occupational class for children of too low a grade to attend the special M.D. school. A table is given showing that of 593 milk samples (town and country) examined since 1900, 48, or 8 per cent., proved to be tuberculous. Additional accommodation for the staff is needed at the hospital and also more cubicles for patients with a view to preventing "cross infection."

Dr. Simpson would like to see the practice of giving diphtheria antitoxin in clinically suspicious cases, while the result of the swab examination is being awaited, more generally adopted. The present dental

staff is insufficient to cope with the work. Out of 2129 children referred for treatment, only 914 received treatment. Some more adequate scheme is needed to secure the provision of spectacles for the school-children who are found to need them. Amongst other needs mentioned by Dr. Simpson are the "scrapping" of the older types of school desks and the provision of electrical treatment at the massage clinics, and he includes in his report an extract from a report by Dr. Veitch Clark strongly recommending the establishment of an open-air school and also that the windows of the class-rooms of future schools should be casement windows which will open right back to the wall so as to enable the class-room to be converted into an open-air room when desired.

Reading.

Dr. H. J. Milligan tells us that housing conditions are still unsatisfactory. The census returns show that about 10 per cent. of the houses are occupied by two families. Reading is a town well adapted for the use of shelters for consumptives, and the 33 provided by the Council have all been fully used during the year. The treatment with collosol calcium has been tried on a small scale. The 13 cases treated were all cases who had had considerable hæmorrhages and tubercle bacilli in their sputum. None of them had hæmorrhage after treatment, but in no case did the tubercle bacilli disappear from the sputum.

Dr. Milligan thinks the time has now come when only fully trained nurses should be allowed to qualify as midwives. He estimates that, as the result of the extension of the infant welfare movement, two-thirds of the children in the borough now come under the supervision of the centres. The damage from the seven notified cases of ophthalmic neonatorum was high, one case with corneal nebula, and another with one blind eye, and the remaining eye damaged. There were 253 confinements in the municipal maternity home with no maternal deaths and 5 stillbirths. The staff of midwives delivered 208 and the remaining 45 were attended by the doctor of their choice. Two years' experience have proved the success of the home and the medical arrangements. At the ante-natal clinic it is found that very few of the women are willing to undergo dental treatment. The day nursery has been closed, an investigation having shown that foster-mothers are forthcoming to meet the normal demand.

The farmers in the Reading district specialise in Grade A (tuberculin-tested) milk, and there are now about 20 in the district supplying this class of milk, which is sold in Reading at only 1d. per quart above the price of ordinary milk. The spread of the clean milk movement in Reading is due to the energetic propagandism of the National Institute for Research in Dairying. It is to be hoped there will soon be many more such institutions in different parts of the country.

In his school report Dr. Milligan refers to the "almost complete absence of rickets" and to the great effects to be expected in after years from the attention now given to the teeth of the school-children. He regrets, however, that so many parents do not yet appreciate the importance of early dental treatment for their children.

THREE SMALLER BOROUGHES.

Ealing.

Dr. Thomas Orr reports that scarlet fever and diphtheria have been prevalent throughout the year and that diphtheria caused a death-rate of 0.41. The gross pollution by sewage of the Brent continues, but an improvement is expected when the alterations at the Wembley sewage works are completed. A serious nuisance is caused by a refuse dump at Northolt, outside the borough, owned by one of the metropolitan boroughs, and Dr. Orr makes out a good case for new legislation conferring powers on local authorities to prevent the establishment of such refuse dumps in their districts. Housing difficulties still remain, but good work has been done in improving the older houses. Six cases of lead poisoning in the borough

were attributed to the drinking of beer contaminated by lead-glazed containers. The containers were removed immediately on the discovery of the cause of the outbreak.

In his school report, Dr. Orr states that all cases of adenoids are recommended for operation and cases of enlarged tonsils which suffer from (a) repeated sore throats, (b) repeated colds, (c) obstruction, (d) deafness, or earache, or (e) "winter coughs." Of the cases operated on in past years 57.6 per cent. showed a definite improvement in health, while of those not operated on only 2.2 per cent. showed an improvement. It would be interesting to know in such statistics the exact nature of the tonsil operation and if enucleation is found to give better results than less radical operations. Dental treatment and inspection is very thorough in Ealing. More than two-thirds of all the school-children were inspected and the percentage of "leavers" with sound teeth is now over 70, or about double what it was in 1915.

Hove.

Dr. Augustine Griffith reports that no working-class dwellings were erected in 1922 and that at least 100 are badly wanted. The Council have passed a scheme for 20 more, but they are not yet begun. The water-supply had to be cut off during the evening and night up to June, since when there has been a continuous supply. The new crushers for house refuse have been a success and during 1922 for the first time the refuse has been disposed of without nuisance and with benefit to agriculture. An outbreak of scarlet fever in connexion with a school is attributed to healthy carriers.

Tunbridge Wells.

Dr. F. C. Linton gives the death-rate corrected for age and sex constitution as 12.5. He again draws attention to the unsuitability of the premises in the basement of the health office for use as a maternity and child welfare centre. Owing to this cause antenatal work has not yet been undertaken. The extension of the administrative block of the isolation hospital, sanctioned in 1914, has not yet been carried out. In his school report Dr. Linton says: "The standard of school cleanliness has not been high and has not shown signs of rising during the past ten years." Perhaps Tunbridge Wells is like some other health resorts and the mothers are so taken up with the visitors that they have not time to attend to their own children.

SCHOOL MEDICAL SERVICE.

Kent.

In 1914 the average number of children on the school roll in Kent was 84,707 in 446 schools, compared with 79,683 in 441 schools in 1922. This is attributed to the fall of the birth-rate and to the committee's policy of excluding certain children under 5. There has thus been a marked diminution of the children medically examined, 21,947 children being seen at routine inspection, and 4866 of these being referred for treatment. In addition there were 4657 special examinations and re-inspections. Children excluded by the nurses for uncleanness totalled 1235, against 1219 last year. Altogether 142,620 children were examined by the school nurses, necessitating 2639 nurses' visits to schools, and about 7 per cent. of these children were found to be verminous in different degrees. Dr. Alfred Greenwood suggests that the wearing of hair in plaits would reduce these figures considerably. The cases of enlarged tonsils and adenoids numbered 4429, 1104 of them requiring operative treatment. Twenty-five cases of phthisis were recorded during the year, while phthisis was suspected in 109 cases. Also there were found 65 cases of non-pulmonary tuberculosis. There was a marked increase in the incidence of infectious disease; the total number of closures was 204, compared with 42 the previous year. Influenza accounted for 65, measles 60, and whooping cough 45. Altogether 60 cases of ringworm were treated by X rays with an

average of 60 days between treatment and readmission to school. Of the 193 cases treated by other methods, the average absence was 145 days. Special investigations were held by the assistant school medical officers into (1) the occurrence of goitre in school-children, (2) the practice of breathing exercises in schools, (3) rickets, (4) postural deformities, and (5) water-supply of schools. All these inquiries have elicited interesting information. In one school in the Cranbrook area enlarged thyroid appeared in 20 girls and 8 boys out of a total of 180 children. Among girls of 13 to 14 there were eight cases and four among boys of the same age. Four girls and four boys of 8-9 years of age showed enlargement. Three families accounted for seven of the 20 girls. It was found that the old method of conducting breathing exercises still prevails, the exercise consisting of breathing in through the nose and out through the mouth in the 46 schools examined; handkerchiefs were made use of in only seven schools, and mouth-breathers selected for special examination in only three schools, the reason given being that there was little time available for such action. The shortsightedness of such a policy is very obvious to a teacher with any knowledge of the influence of health on educational results, and it is comforting to reflect that the newest crop of students from training colleges are alive to this. The report on lavatory accommodation in 413 schools is illuminating. The washing accommodation is absurdly inadequate; 29 schools and 10 departments have no washing utensils whatsoever. Yet there is no doubt that the figures are better than in quite a large number of districts, which goes to show how much educational effort is still required in this department of school hygiene.

Eccles.

An open-air school with accommodation for 40 children at Peel Green has now been provided for the borough of Eccles. The premises consist of a large room, 63 by 23½ feet, with a covered verandah in front. The room is closed at night by sliding partitions which run on overhead tracks and which are used in the daytime to divide this large room into four separate class-rooms. The eastern part of the room is used as a dining room, and the two western parts as rest rooms. During class hours the folding beds are stored in the western portion, and the two central rooms are used as class-rooms. Along the north side a corridor runs dividing the class-rooms from the bath-room, kitchen, teachers' room, and store-room on the other side. The bath-room contains three foot-baths with hot and cold sprays, and dressing boxes for six children. Three meals a day are provided—lunch from 9.30 to 10.30 A.M., consisting of porridge with sugar or treacle and milk or bread and milk; a two-course dinner at 12.30 P.M. and tea at 4.30 P.M., consisting of cocoa, bread, butter and jam or bread and dripping. Cod-liver oil and malt, or Parrish's food and cod-liver oil are given after each meal. Breathing exercises are taken twice daily, as also a tooth-brush drill. There is no mention in the time-table of regular bathing. The daily cost of food per head worked out at 9.2 pence; including car fares and cod-liver oil and tooth-brushes the cost was 10.5 pence. Of the total, £197 17s. spent in the seven months since the opening, £166 2s. was refunded by the parents, the full charge being 5s. a week. The number of children examined at routine inspection was 2462, and of these 613 were recommended for treatment, 318 receiving treatment during the year. Dr. J. E. Spence reports that the nurses' routine examination of all school-children twice a year has resulted in a much higher standard of cleanliness. It would seem unfortunate that the lavatory accommodation in the schools is either inadequate, or where adequate, that towels and soap are often not available. Dr. Spence pleads with the teachers to impress upon the children a reasonable standard of personal cleanliness, supplementing lectures on personal hygiene by the simple but effective method of sending them out to wash their hands when necessary.

"Audi alteram partem."

OPIUM IN SEPTIC PERITONITIS.

To the Editor of THE LANCET.

SIR,—Mr. H. W. Carson's article on the Evolution of the Modern Treatment of Septic Peritonitis, and your editorial on the same subject in THE LANCET of May 19th, raise the question of how the surgeon is to reconcile the adoption of the method of the post-operative administration of opium, which was so recently thought to be disastrous and which is now rapidly gaining favour, with the present conception of the physiology of absorption from the peritoneal cavity. From recent experimental research carried out in the University of Toronto I have demonstrated that in diffuse septic peritonitis there is a fatal absorption through the thoracic duct. This finding explains quite clearly why good results follow the administration of opium. The flow of lymph through the thoracic duct is caused by: (1) respirations—exerting a pumping action on the duct as it traverses the mediastinum; (2) muscular activity—causing an intermittent increase in the intra-abdominal pressure; (3) the suction of the blood-stream in passing the opening of the thoracic duct—a factor hitherto unrecognised.

These are the three main factors, and the action of opium on them is as follows: (1) It slows the respirations, thus diminishing the lymph flow. (2) The abdomen is put at rest; vomiting, which produces a marked increase in the lymph flow, is lessened. (3) The blood-stream is slowed and the suction on the duct is reduced to a minimum. The beneficial action of the Murphy method of treatment may also be explained in the light of this new conception of the physiology of absorption from the peritoneal cavity and the lumen of the bowel.

Shortly after the research referred to was done I drained the thoracic duct in a girl of nine suffering from pneumococcic peritonitis, and she made a very pleasing recovery. Attention is drawn to this phase of peritonitis in the hope that the acceptance of the principle may lead to the formation of a better method of treatment of septic peritonitis.

I am, Sir, yours faithfully,

Toronto, June 4th, 1923.

WM. A. COSTAIN, M.B.

TOXIC SYMPTOMS FOLLOWING THE ALKALINE TREATMENT OF PEPTIC ULCER.

To the Editor of THE LANCET.

SIR,—In view of the fact that I have for several years been a strenuous advocate of the medical treatment of gastric and duodenal ulcer in preference to surgery, I think it only right to draw attention to the possibility of toxic symptoms arising as a result of using very large doses of alkalies. Sippy, who was the first to recommend this treatment with the object of completely neutralising the acid of the gastric juice, has not referred in any of his papers on the subject to the toxic symptoms which may result. In a recent paper from the Mayo Clinic, Hardt and Rivers¹ describe the toxic symptoms which may develop in cases in which it is impossible to neutralise the acid completely. The patient is at first unduly introspective and nervous. He then complains of difficulty in taking his milk. After a time headache, nausea, and vomiting occur. The patient becomes apathetic and drowsy, and in one of their cases death ensued. In every instance the urea in the blood became greatly increased, and albumin and casts appeared in the urine. In some there was evidence of kidney disease before the symptoms developed, and in the fatal case definite

¹ L. L. Hardt and A. B. Rivers; Arch. Int. Med., xxxi., 171, 1923.

chronic nephritis was found. I have met with three similar cases in private patients, though none in hospital, during the last three years. In one case the patient had only one kidney and this was affected with pyelitis. In the other two patients a moderate degree of pyloric obstruction was present and there was an extreme degree of hypersecretion. In one of these death occurred in spite of the early cessation of the alkaline treatment. The urea content of the blood was greatly increased in all three cases.

It is impossible at present to say what is the cause of the toxic manifestations. But it seems clear that no case in which the kidneys are diseased should be subjected to the full alkaline treatment, and the same is true when partial pyloric obstruction is present in spite of Sippy's advocacy of the treatment in such cases. If any suspicious symptoms develop, a blood-urea estimation should be made and the treatment discontinued until it is ascertained whether it is excessive; in that case the treatment should be modified.

For ulcers associated with renal disease treatment by diet, olive oil, and belladonna in the manner I have described, with only small doses of alkalies, may give sufficiently good results, but if pyloric obstruction is present, even in a mild degree, it is probably wise to recommend gastro-enterostomy without further delay.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, June 17th, 1923.

TREATMENT OF HÆMORRHOIDS.

To the Editor of THE LANCET.

SIR,—Mr. R. M. Rowe's article on hæmorrhoids in THE LANCET's series on Modern Technique in Treatment contains so much that is excellent, and summarises the subject of the symptoms and diagnosis of hæmorrhoids so clearly, that I trust it will not be considered churlish on my part to offer a few criticisms with reference to what he has written about the treatment of internal hæmorrhoids—especially the treatment by means of injection.

Mr. Rowe deals at some length with the palliative treatment of internal hæmorrhoids, and includes under that heading a method involving a week's rest in bed, special diet, and general and local medication. Now, palliative treatment implies that symptoms only are dealt with, and that the underlying pathological condition is not removed. All that the rather heroic palliative treatment, which Mr. Rowe suggests, can accomplish is to control hæmorrhage temporarily. Considering that treatment by means of injection not only produces immediate cessation of both bleeding and prolapse, but ultimately effects a permanent cure of the hæmorrhoids in the large majority of cases, and that this treatment—contrary to what Mr. Rowe hints—is applicable not only to the earliest cases but also to the most severe, I think it questionable whether it is ever justifiable to condemn a patient to a week's confinement to bed without at least explaining to him the advantages of the treatment by means of injection. By this means his piles can be permanently cured without any absence from business and without the use of unpleasant and messy local applications.

Mr. Rowe would limit the scope of the treatment by means of injection to such cases as present a single pile mass, which only occasionally prolapses from the anal orifice. I suspect that the explanation of this limitation on his part is that his idea of the effects of injection is radically erroneous. He—like many others—appears to believe that injection of a 20 per cent. carbolic solution produces thrombosis of the pile treated. As a matter of fact, thrombosis very rarely occurs, and, when it does, it is due to faulty technique. The actual effect of injection is to produce a rapid effusion of lymph into the sub-mucous tissue of the pile; this subsequently becomes organised and contracts, thereby obliterating the vessels of the pile and producing adhesion between the mucous and muscular layers. Thrombosis, if it

occurs, results from the use of too strong a solution or from using too much. It is evidenced by severe and long-continued pain, which completely cancels the chief advantages of this method of treatment. When I have stated that I have had only one definite instance of thrombosis amongst some 3000 to 4000 cases, I have said enough to show the great rarity of this accident in a long series of cases treated by injection. "Septic thrombosis" I have never met with. Mr. Rowe gives the oft-repeated advice that only one pile should be treated at a time, and seems to be under the common delusion that two injections for each pile are likely to suffice. I fear that, if his directions in this respect are followed, the treatment will fall into disfavour, because recurrence will be the rule rather than the exception. My own practice is to inject as many hæmorrhoids as can be brought into view through a Kelly's speculum at the first sitting, and to repeat the process at intervals of a week until all visible traces of the hæmorrhoids have disappeared. I find that the average number of injections necessary to effect this is four; in some cases three are sufficient, whilst others may need as many as six. During the whole of the treatment rest in bed is unnecessary, and there need be no interference with either business or pleasure, beyond the avoidance of strenuous exertion on the actual days of the injection. Meanwhile no ointments or suppositories are required.

My technique was described in an article in THE LANCET for March 18th, 1916, and my results were summarised in an article published in the *Practitioner* last July. I am, Sir, yours faithfully,

ARTHUR S. MORLEY, F.R.C.S.

Gordon-square, W.C. 1, June 16th, 1923.

DELAY IN GIVING DIPHTHERIA ANTITOXIN.

To the Editor of THE LANCET.

SIR,—May I aid in supporting the above appeal, so properly put forward by Dr. F. F. Caiger in your issue of June 9th, by quoting the following extract from page 490 of my report on the health of the Borough of Croydon during 1922.

"Fatality in diphtheria may be said in practically all cases, except the toxic variety, to be determined by the length of time allowed to elapse before the giving of antitoxin. Were the practice prevalent of giving no more than 2000 units antitoxin whilst awaiting the result of a swab in any clinically suspicious case, the present mortality of the disease would undoubtedly tend to be diminished. The nasopharyngeal type of case which tends to the greatest fatality further seldom requires confirmation bacteriologically."

Were the practitioner able to see all cases of alleged diphtheria, have them confirmed or otherwise bacteriologically, and, if necessary, removed to hospital within the first 24 or even 36 hours of the onset of the disease, no great harm might probably result. This, however, is exactly what does not always happen.

That suspicious throats should be sent into hospital for diagnosis, as suggested by one of your correspondents as a matter of course, is to use the fever hospital for a purpose for which it was never intended on any general scale, not to mention the additional expense thereby involved, the unnecessary trouble caused to prevent cross infection, and the occupying of beds, it may be, required for actual cases of diphtheria awaiting admission, and probably their only opportunity of obtaining antitoxin. If antitoxin be given as a routine measure in all reasonably suspicious cases clinically resembling diphtheria, a heavy item in the present case mortality of the disease would be removed, an item whose removal at present is almost entirely in the hands of the general practitioner. The occurrence of anaphylaxis, to be expected in only some 5 per cent. of cases, is not a difficulty of sufficient magnitude to be more than seriously considered when the possible reduction of the death-rate in diphtheria is at stake.

I am, Sir, yours faithfully,

Public Health Department, Town Hall, K. SIMPSON.
Croydon, June 18th, 1923.

To the Editor of THE LANCET.

SIR,—As a panel practitioner in a working-class district I sympathise very much with Dr. F. F. Caiger's suggestion (THE LANCET, June 9th) to administer antitoxin in all suspected cases of diphtheria. I do not follow the practice myself as a rule, though I do occasionally where I think the circumstances warrant it. I generally follow the alternative course of sending the child away direct to a M.A.B. hospital if I strongly suspect, but am not sure, of the diagnosis of diphtheria. I think it is probable that the death-rate from diphtheria will be materially lowered if antitoxin in sufficient doses were given as a routine practice in every case of suspected diphtheria. No doubt in some instances it would be difficult to overcome the prejudices of the parents, but diphtheria is feared so profoundly, and rightly, by the working people in industrial districts that there would be no difficulty if the doctor had made up his mind to adopt the practice as a routine. In districts like Bermondsey—and I believe elsewhere in London—the serum can be obtained gratuitously at the town hall, and I personally always keep a stock in hand obtained in this way. I do not think that there is any risk of anaphylaxis, because I understand that the highest authorities agree that repeated injections can be given, daily or at intervals up to ten days from the first injection, without invoking anaphylaxis. The suggestion has been made to appoint a consultative M.A.B. officer for throats, but I hardly think such an appointment would be of much value, as in the cases that turn out serious very often no possible diagnosis can be made by inspection or by clinical signs alone until it is too late.

On the whole I agree with Dr. Caiger. There are two alternatives before the doctor: (1) Send any case that may possibly turn out to be diphtheria into hospital the moment it is first seen, or (2) give it 6000 or 8000 units of antitoxin instantaneously, and await results of bacteriological investigation of the swab.

I am, Sir, yours faithfully,

June 19th, 1923. ANOTHER PANEL PRACTITIONER.

IN MEMORY OF JOHN CHIENE.

To the Editor of THE LANCET.

SIR,—As Prof. G. L. Gulland wrote in THE LANCET last week, time spent with John Chiene is a happy memory to many of his old students. I arrived in his wards in the Old Infirmary in the summer of 1879, silly in going to the wards before I knew any anatomy, but there were others as foolish. Mr. Chiene soon discovered there were some of his following who knew nothing of anything, and in particular that we had no idea of the great new principle of antiseptics in surgery. Shocked and full of pity, he assembled us infants in his wards for half a dozen lectures half an hour before the ordinary ward visits, determined that, though we were only paying for our infirmary tickets and paying nothing to him, we should at least not be wasting all our time. "To get a grip of principles, and to learn . . . to draw conclusions from his observations," Prof. Gulland truly says, was the object of his teaching, as it was also of the Edinburgh School, with the result that students who went through the school then were less slaves to authority and "the books" than others. The individual point of practice I most clearly trace back to Chiene is the use of elastic wove bandage and cotton-wool in the immediate treatment of black-eyes and sprains; most valuable and never noticed in print since, so far as I have seen, except by Mr. R. H. A. Whitelocke, of Oxford. A patient of mine sprained his ankle at 5.30, at 6 it ached, at 6.30 it had swelled, he could not put his foot to the ground and could not dine in mess. Hot water, cotton-wool, and elastic bandage, applied and re-applied, fixed him so that he bicycled 40 miles next day to an eagerly anticipated party. He was very grateful, but his gratitude was due to John Chiene.

I am, Sir, yours faithfully,

Waterlooville, June 18th, 1923. W. E. HOME.

FIBROMA OF THE OVARY.

To the Editor of THE LANCET.

SIR,—The account of a case of fibroma of the ovary with a summary of the literature by Dr. Ambrose W. Owen in your issue of June 16th, will be read with interest by all surgeons who have to deal with such.

I operated recently on a woman aged 73, who was sent into hospital by Dr. A. P. Walters, of Burgh-by-Sands, on account of an ovarian tumour he had previously tapped. Examination per vaginam detected a firm, hard mobile tumour joined to an ovarian cyst of the dimensions of a large football. The hard mass distinctly suggested a fibroid. The cyst proved to be multilocular, was free from adhesion, and turned out easily enough, but incorporated with its base was a fibroma about the size of a tomato. There was a broad connexion between the cyst and the fibroma and the latter had a rather long pedicle, whilst the broad ligament was opened up as far as the appendix region. It was obvious to those present that a fibrous tumour had been removed along with the cyst, and I halved the growth and sent a portion to Mr. Richard Muir, of Edinburgh, for examination, who wrote: "It is a very typical fibroma composed of well-formed fibrous tissue." This verdict was subsequently confirmed by Prof. S. G. Shattock.

The point of interest is the exact origin of the fibroma which at no point was attached to the uterus. Mr. Alban Doran, who also saw the specimen, considered that the fibroma arose from the utero-ovarian ligament. Dr. Owen's paper indicates how seldom such fibromas are met with in the experience of surgeons who operate upon hundreds of cases of ovarian disease. In his case there was abundant ascites and the tumour weighed 19½ lb., whereas in mine the tumour was small and there was no free peritoneal effusion. The patient's recovery was uneventful.

I am, Sir, yours faithfully,

H. A. LEDIARD,

Surgeon to the Cumberland Infirmary.

Carlisle, June 17th, 1923.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council held on June 14th diplomas of Fellow were conferred on the following 24 candidates out of 91 candidates who presented themselves at the recent examination:—

W. Anderson, Aberdeen; H. A. Brookes, Edinburgh University and London; A. G. Bryce, Manchester and St. George's; C. Hope Carlton, Oxford and St. Mary's; G. R. E. Colquhoun, Cambridge and St. George's; D. I. Currie, Leeds and London; F. P. Fouché, Edinburgh and Guy's; G. J. Gillam, Toronto and St. George's; W. J. Lytle, Belfast and London; N. Makar, Cairo and St. Thomas's; P. J. Moir, Glasgow and London; J. W. G. Phillips, St. Mary's and London; J. McL. Pinkerton, Glasgow and St. Bart's; J. E. Purves, Edinburgh; S. D. Rhind, St. George's; W. Salisbury, Bristol and London; R. S. Scott and W. Shaw, Cambridge and St. Bart's; N. R. Smith, Sydney and Guy's; G. F. Syme, Guy's; D. R. Wheeler, Belfast and London; E. R. Wheeler, King's College; R. L. Williams, Cambridge and St. Bart's; and S. H. Woods, Dublin, London, and Guy's.

Licences in Dental Surgery were conferred upon the following 76 candidates:—

G. W. Aaronson and E. J. Anderton, Royal Dental; D. J. Andrews, Bristol; G. Armytage, Royal Dental; L. Ayliffe, Manchester; Caroline W. Bailey-King, Royal Dental; H. P. Baylis, Guy's; A. W. Bell, C. A. Bennett, and P. Bentley, Royal Dental; J. V. Bingay, Guy's; F. R. Boetius, London; W. L. Boness, Guy's; W. R. B. Booth, Manchester; W. J. Buttle and F. R. Christian, Royal Dental; J. W. Clark, Durham; D. G. Comber, Royal Dental; F. Crone, Guy's; J. W. Curley, Royal Dental; A. S. Davies, Guy's; A. C. Deverell and G. S. Dingley, Royal Dental; G. B. Drury, Birmingham; S. J. du Plessis and J. U. H. du Preez, Royal Dental; G. A. Edwards, Leeds; R. Edwards, Guy's; C. Fletcher, H. G. L. Fletcher, A. T. S. Fourie, and H. A. S. Gaffyne, Royal Dental; W. Gardner, Sheffield; P. N. Gibbs, Birmingham; A. S. Gosling, Royal Dental; H. Haines, Birmingham; H. D. Hall, Guy's; G. M. Hay, Royal Dental; E. V. Hayes and F. L. Haynes, Guy's; L. H. Head, Durham; J. Hegarty, Liverpool; W. A. Linnell, Manchester; T. G. Lloyd, Guy's; A. C. Maguire and I. Mann, Royal Dental; C. B. May,

Birmingham; R. N. Merrett, London; R. Milburn and E. W. Pedley, Royal Dental; H. L. Pitt, University College; C. Pratelli, Royal Dental; L. F. L. Pringle, Durham; W. N. Reynolds, London; J. B. Roberts and V. R. Roberts, Guy's; Gladys M. Seal, Royal Dental; P. B. Sharp, Royal Dental; J. E. B. Smith, Guy's; C. R. Smitheringale, Royal Dental; L. Smuts, London; M. R. Somers, Royal Dental; E. L. Sprong, Guy's; F. J. Stay, H. C. Steyn, H. P. Sutcliffe, Janet H. M. Sutherland, D. R. Sutton, and L. A. Trace, Royal Dental; J. L. T. Urquhart and F. N. Van der Pant, Guy's; and I. M. van Dockum, V. M. Wallis, J. W. Watts, H. J. V. Webster, and S. Winer, Royal Dental.

The following were elected examiners:—

Board of Examiners for the Fellowship: Mr. W. Wright, London Hospital. Second Examination of the Conjoint Board: Mr. H. A. Harris. Final Examination of the Conjoint Board, Midwifery: Dr. D. W. Roy.

A letter was read from Mr. F. F. Burghard, King's College Hospital, resigning his membership of the Court of Examiners. —The President reported that a vacancy would be occasioned by the retirement of Mr. Norman Bennett from the Board of Examiners in Dental Surgery.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Dr. T. W. Naylor Barlow, of Wallasey, has been elected president of the society for the session 1923-24. He will be installed on Oct. 19th, and will preside at the annual dinner of the society on the evening of the same day.

LONDON HOSPITAL MEDICAL COLLEGE.—A lecture on the Stomach from the Radiologist's Standpoint will be given by Dr. G. E. Vilvandré on June 28th, at 4.15 P.M., in the Anatomical Theatre of the College. The lecture is intended for senior students of the hospital and post-graduates.

PADDINGTON TUBERCULOSIS DISPENSARY.—The annual meeting will be held at the Town Hall, Paddington, on Monday, June 25th, at 8.30 P.M. The Mayor of Paddington will preside and Sir Robert Philip will be the principal speaker. After the business of the meeting has been transacted a film entitled the Story of John McNeill will be shown.

NATIONAL COUNCIL OF TRAINED NURSES OF GREAT BRITAIN AND IRELAND.—At a meeting held at the club of the Royal British Nurses' Association, 194, Queen's-gate, London, S.W., on June 14th, a presentation was made to Mrs. Bedford Fenwick, President of the Council, of a bound and inscribed copy of the first Statutory Register of Nurses, in recognition of her services to the nursing profession.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.—A meeting of the Executive Committee of this society was held on June 14th under the chairmanship of Lord Willoughby de Broke. The following resolution was carried unanimously:—

"That the Executive Committee accepts the Trevethin Report as a document supporting the essentials of the policy of the Society for the Prevention of Venereal Disease, as defined in their policy pamphlet, and especially welcomes the recommendation 'that the law should be altered so as to permit properly qualified chemists to sell ad hoc disinfectants, provided such disinfectants are sold in a form approved, and with instructions for use approved by some competent authority,' as set forth in Clause 14 of the Report."

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—General refresher courses and special courses in cardiology, children's diseases, dermatology, and ophthalmology have been arranged by the Fellowship of Medicine during July and August. Copies of the syllabus of each course and tickets of admission can be obtained from the secretary to the Fellowship of Medicine, at 1, Wimpole-street, London, W. The special course in neurology, to be given at the West-End Hospital for Nervous Diseases from June 25th to July 27th, will include clinical work in the out-patient department and special lecture-demonstrations dealing with the diagnosis and treatment of common nervous disorders.

EPSOM COLLEGE: "FRANCE" PENSIONS.—The Council will shortly award several "France" pensions of £30 a year to medical men. Candidates must be not less than 55 years of age, and their income, independent of any allowance from the College, must not exceed £100 a year. The Council will also award one "Grewcock" pension of £50 a year. In this case there is no limitation as to age, but candidates must be legally qualified medical men who have retired from professional work, and who, in the opinion of the Council, are in need of the pension. There is the same income-limit as in the case of "France" pensioners, and special consideration will be given to the claims of candidates having association with Worcestershire, Lincolnshire, or Carmarthenshire. Forms of application can be obtained from the secretary, Mr. J. B. Lamb, 49, Bedford-square, London, W.C. 1.

ROYAL LONDON OPHTHALMIC HOSPITAL.—It has been decided that women shall be eligible for election to the Committee of Management, and Lady Cooper and Lady Lister have been duly elected to serve as members of the committee.

THE LATE DR. F. P. FERRAN.—The death took place last week of Dr. F. P. Ferran, who was at the time a prisoner in the internment camp at the Curragh. Death was due to pneumonia. He was a native of the North of Ireland, and was educated at Queen's University, Belfast, where he took his medical degrees in 1910. He was medical officer of Foxford, county Mayo, and a member of Dail Earrann for the united constituency of Sligo and East Mayo. He voted against the Treaty, and was believed to have taken an active part in hostilities on the Republican side.

CREMATION SOCIETY.—The Transactions of the Cremation Society of England, No. XXXIV., is an important document, containing not only the report of the council and the balance-sheet but the proceedings of a conference of cremation authorities presided over by Sir Malcolm Morris at the Guildhall, London, on Oct. 26th, 1922. Among the questions discussed at this conference were the substitution of cremation for burial, the best means of spreading information on the subject, and the doctor's fee for the medical certificate. As Dr. Chalmers Mitchell forcibly pointed out at this conference, "The dead are very much more numerous than the living, and every year they are getting more and more numerous, and the living cannot afford the present arrangements." During 1922 the number of cremations which took place in Great Britain was 2009, or 87 more than in 1921, but in the provinces there has been a decrease. The Transactions also contain notes on various cremation societies, a list of British crematoria, the steps to be taken in order to arrange for cremation, and other useful information, and is published at the offices of the society, 52, New Cavendish-street, London, W.1 (price 1s. 6d. post free to non-subscribers).

ST. THOMAS'S HOSPITAL: NEW LABORATORY.—On the occasion of the prize distribution on June 13th the new laboratory, the gift of the Dunn trustees to the hospital, was declared open by the Marquis of Cambridge. During the proceedings Sir Walter Fletcher, F.R.S., gave a description of the laboratory, and spoke of the work done in the former laboratories, particularly that valuable work relating to trench nephritis which had proved so useful during the war and in relation to the results of kidney disease generally. Another more recent development of the same work had notably increased the safety of certain kinds of surgical operation; at the present time the biochemical laboratory was engaged in chemical work which the insulin treatment of diabetes rendered necessary. The work of the biochemical laboratory was, however, hampered by an artificial regulation whereby animal experiments might be performed in the medical college, but not in the hospital. Sir Jeremiah Colman, on behalf of the Dunn trustees, asked acceptance of the laboratory. He explained that Sir William Dunn, a successful South African merchant, had appointed the directors of the Commercial Union Insurance Company to distribute the trust money. This money was now either exhausted or ear-marked, but he wished the hospital to accept a further £5000 for scientific instruments. Sir Arthur Stanley, treasurer, cordially accepted the gifts on behalf of the hospital.

LIVINGSTONE COLLEGE, LEYTONSTONE.—Commemoration day was held at the college on June 13th, Sir Leonard Rogers, F.R.S., being in the chair. Short statements were made by the Principal, Dr. Tom Jays, and the Treasurer, Mr. R. L. Barclay, as to the work of the past year, and the financial position of the college, it being pointed out that if a sufficient number of students were sent to the college regularly there would be no need to appeal to friends for financial support. An urgent appeal was necessary, however, in order to enable the work to be carried on until the number of students should be so increased as to make the college self-supporting. About £500 is needed before the end of the current financial year. Sir Leonard Rogers said that he felt the work of Livingstone College was more needed than ever at the present time, owing to the shortage of medical men and women working in the mission field. To his mind the most important work of Livingstone College was to train these missionaries in looking after their own health when they went out to distant parts of the Empire, where they often lived far from medical aid, and for want of the knowledge they could gain in a few months they often sacrificed health. "Another great feature of this work," he said, "is that all those who go through the training here are able to treat a large proportion of the ailments of these people and able to show the Gospel to them in a way they could not otherwise do." Sir Leonard Rogers referred particularly to leprosy; he felt strongly that if missionaries

who were going out to work amongst lepers were sent to be trained at the college it would be very beneficial in helping to carry out the cure of leprosy. He spoke of the problem of segregation and prophylaxis, and the difficulties in carrying out these measures. When that could be done an enormous advance would be made. Mr. J. M. Brand, an old student of the college, who has been working in South India as a missionary of the Strict Baptist Mission, described the benefit of the training, as regards the ability given to missionaries to take care of themselves and of their native workers in unhealthy places and as regards the confidence with which it enabled them to go about pioneer work. Mr. T. L. Suffill, another former student, now of the Sudan United Mission, home on furlough from Nigeria, also told of the great value of the knowledge he had gained as a student at the college.

THE LATE MR. A. McDONNELL.—Mr. Alexander McDonnell, who died on June 14th, was medical officer of Stamford Hill and St. Michael's Maternity and of the Stoke Newington District Post Office, and well known as a practitioner in the North of London. He qualified L.S.A. in 1884 and took the L.R.C.S. Edin. and L.M. in the following year. He was President of the Four Provinces of Ireland Club.

CANCER CHARITY, MIDDLESEX HOSPITAL.—The report of this charity for the year 1922 shows that at the beginning of the year 76 patients were under treatment in the wards, while during the 12 months 513 patients were admitted and 86 remained at the end of that period. In the previous year the number of admissions were 505. The average daily bed occupancy was 86.13 as compared with 85.74 for 1921, and the average length of stay was 62.37 days as compared with 60.65 in the previous year. Each in-patient cost on an average £4 4s. per week, a decrease of about 3s. 6d. in the previous year's average. In the out-patient department there were 191 new cases treated and the attendances numbered 708. In 1921 the figures were respectively 234 and 789. The average cost for each out-patient was £1 2s. 4d., the cost during 1921 being 19s. 2d. The income and expenditure account shows an increase of £428 in the ordinary income (from £15,758 to £16,186), while the extraordinary income which included special grants from the Voluntary Hospitals' Commission and preliminary grants from Combined Appeal Fund rose from £2850 to £4437. The subscriptions for 1922 amounted to £1530 as compared with £1191 in 1921.

IRISH FREE STATE. ARMY MEDICAL SERVICE.—Our Dublin Correspondent writes: Until the recent statement made by General Mulcahy, Minister of Defence, regarding the Army Medical Service, no public information had been given as to the amount of control exercised by the Army medical authorities in the matter of appointments to the Army Medical Service. There had been some uneasiness lest political considerations were being allowed to weigh against professional competence. General Mulcahy's statement, however, was thoroughly reassuring. He said that the Director of Medical Services was appointed by the Minister, and was solely responsible for the efficiency of the Service. All appointments were made with Ministerial sanction on the Director's recommendation. General Mulcahy, giving further details regarding the Army Medical Service, stated that the commissioned ranks at present consisted of 86 lieutenants, 45 other commissioned officers, 15 probationers, 17 dentists, and 30 nurses, together with the headquarters' establishment. The Minister took the opportunity of expressing the gratitude of the Government to Dr. Maurice Hayes for his admirable work in organising a medical service with great rapidity in a time of exceptional difficulty.

MEDICAL GOLFING SOCIETY.—The annual summer meeting was held at Addington Golf Club on June 14th. Over 90 members competed for various prizes, all competitions being against bogey. H. D. Gillies (+2) won THE LANCET Challenge Cup and memento for the best scratch return (4 up); also the Henry Morris Challenge Cup and society's gold medal for best handicap return with 2 up. Other results were as follows:—Class 1: Handicaps 9 and under. 1st prize, Sir Richard Cruise (2), 1 up (H. D. Gillies with return of 2 up being ineligible for this prize). 2nd prize, Jocelyn Swan (6), G. Dawson (4), Gordon Lane (9), Sir K. Goadby (8), tied with all square. Best last 9 holes: Sir K. Goadby and Gordon Lane, tied with all square. Class 2: Handicaps 10 and over. 1st prize, C. M. Hinds-Howell (10), J. Cuning (12), N. B. Benjafield (16), H. L. Hatch (15), J. Clarke (14), tied with all square. Best last 9 holes: J. E. Coulson (11), L. Bathurst (11), tied with 1 up. Foursome-sweepstakes: 1st prize, Bruce Hamilton (12), and G. A. Sutherland (6). 2nd prize, Sir R. Cruise and Gordon Lane tied with C. R. Salisbury (16) and C. H. Housden (18), and with J. S. H. Lewis (8) and Murray Thomson (10). All ties will be played off in due course.

WE regret to announce the death on June 19th of Dr. Walter d'Este Emery, soon after his retirement from his position of Director of Laboratories at King's College Hospital.

Joseph Harvey Kemp Sykes, L.M.S.S.A., has been made an Honorary Associate of the Order of St. John of Jerusalem.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—The annual meeting will be held at 1, Upper Montague-street, London, W.C. 1, on Thursday, June 28th, at 4.15 P.M., Sir Arthur Newsholme, the President, in the chair.

CALEDONIAN MEDICAL SOCIETY.—The thirty-eighth annual meeting will be held in the Aberdeen Medico-Chirurgical Society's Hall on Friday, June 29th, at 2.30 P.M., under the presidency of Dr. David Rorie. The annual dinner will take place the same evening at the Palace Hotel, Aberdeen.

SMALL-POX IN ENGLAND AND WALES.—During the week ending June 9th 58 cases of small-pox were notified in England and Wales, the distribution being as follows: Derbyshire 6 (Heanor 5; Clown R.D. 1), Durham 4 (Stockton-on-Tees), Gloucestershire 35 (Gloucester 26, Cheltenham 1, Cirencester 1, Stroud 1, East Dean R.D. 1, Lydney R.D. 1, Stroud R.D. 4), Nottinghamshire 4 (Nottingham 1; Basford R.D. 3), Yorks North Riding 2 (Middlesbrough), Yorks West Riding 2 (Doncaster R.D.), Glamorgan 5 (Cardiff). Since then, apart from the epidemic in Gloucestershire and environs, 10 new cases are reported from Middlesbrough.

DEATH OF MR. CLAYTON FOX.—We regret to announce the death, which occurred suddenly on June 13th from heart failure, of Mr. Hugh Clayton Fox, F.R.C.S.I. For many years assistant surgeon to the Metropolitan Ear, Nose, and Throat Hospital, he was at the time of his death aural surgeon in the Ministry of Pensions and chief assistant in the throat department of the Brompton Hospital for Consumption. A student of the Middlesex and Charing Cross Hospitals, Mr. Fox qualified in 1888, taking his F.R.C.S.I. some years later. He published in 1919 a translation of Dr. Georges Laurens's "Oto-Rhino-Laryngology," a book famous for its excellent elementary teaching, and a second edition was soon demanded. His special interest was in tinnitus aurium. A man of handsome presence and courteous manner, his colleagues and many friends will deplore his sudden and untimely end.

OXFORD OPHTHALMOLOGICAL CONGRESS.—The fourteenth annual meeting of the Congress will take place on July 5th, 6th, and 7th. On July 5th, at 10 A.M., in the Department of Human Anatomy of the University Museum, the Congress will be opened by the Master, Mr. Sydney Stephenson, and a discussion on the Relationship of Dental Sepsis to Diseases of the Eye will then be opened by Mr. W. R. Ackland (Bristol) and Mr. W. Lang (London). The following will take part in the discussion: Dr. T. Harrison Butler (Leamington Spa), Prof. J. Van der Hoeve (Leiden), Dr. S. Lewis Ziegler (Philadelphia), Mr. P. H. Adams (Oxford), Dr. Harold Gifford (Omaha), Mr. N. C. Ridley (Leicester), and Miss M. Gilchrist (Glasgow). The annual general meeting will be held at the conclusion of the discussion. At 2.30 P.M. papers will be read by Lieut.-Colonel H. H. Herbert (Hove) on the Pectinate Ligament and its Connexions; Dr. C. F. Bentzen (Copenhagen) on the Making of the Conjunctival Flap in Elliot's Operation; Dr. H. Gjessing (Drammen) on Clinical Examination of Fistulæ or Filtering Scars after some operations—especially after Holth's iridencleisis with iridotomy; Dr. Harrison Butler on the Organisation of Ophthalmic Clinics and Hospitals. The annual dinner of the Congress, at 7.45 P.M., will be held in the Hall of Keble College. On July 6th, at 10 A.M., in the Department of Human Anatomy, Dr. Sanford R. Gifford (Omaha) will speak on Intra-cisternal Injections in the Treatment of Luetic Optic Atrophy, followed by Dr. K. Lundsgaard (Copenhagen) on Finsen Treatment of Conjunctival Diseases. At 11 A.M. the Doyne Memorial Lecture will be delivered by Mr. H. Moss Traquair on the Differential Characters of Scotomata and their Interpretation. At 12.15 P.M. Prof. J. Van der Hoeve will offer Further Observations on Eye Symptoms in Tuberosc Sclerosis and in Recklinghausen's Disease. At 2.30 P.M. Mr. Rayner D. Batten (London) will discuss (1) the Importance of Fundus Drawings in Clinical Ophthalmology, with Illustrations from Studies of Ophthalmic Draughtsmen. Mr. John D. Batten (London) will contribute a paper on Memory Drawing in Relation to Ophthalmic Drawing, and Prof. Van der Hoeve and Dr. Harrison Butler will speak on Accommodation and on Muscle Recession and Muscle Tucking respectively. At 5.30 P.M. a visit will be paid to the Pitt Rivers Museum. On July 7th, at 10 A.M., in the Department of Human Anatomy,

Mr. R. J. Coulter (Newport, Mon.) will open a discussion on the Diagnosis of Coal-miners' Nystagmus, and Dr. T. Stewart Barrie (Glasgow) will contribute a paper on Colour Vision in Amblyopic Eyes Associated with Strabismus Convergens. In the Scientific Museum Dr. S. Lewis Ziegler (Philadelphia) will demonstrate the Use of the Prism Scale to Neutralise and Centre Spectacle Lenses. The Commercial Museum will be open from 9.15 A.M. daily.

SCOTTISH SOCIETY OF ANÆSTHETISTS.—The annual meeting was held in the hall of the Faculty of Physicians and Surgeons on May 26th, the President, Dr. D. Lamb, being in the chair. The Society considered and adopted a report from the executive committee on the question of the present remuneration and status of specialists in anæsthetics in Scotland. The report shows that the fees in Scotland are at present much below those paid in London and compare unfavourably even with those usual in English provincial centres. Emphasis is laid especially on the following points: 1. At the request of surgeons, anæsthetists frequently reduce their fee to suit the pocket of the poorer private patients in exactly the same spirit as the surgeons themselves do. To this they have no objection, but unfortunately it seems to be a general experience among anæsthetists that what may be termed their standard fee for an administration of average gravity in a patient of ordinary means has come to be looked upon as a maximum to be exceeded upon very rare occasions. It is certain that a considerable number of patients are charged an anæsthetic fee which is too small in comparison with the other expenses associated with the operation. 2. The remuneration paid even to anæsthetists of special experience and acknowledged standing is little if any greater than that accorded to the surgeon's assistant, who is usually a man of junior standing and only at the beginning of his career. 3. In the teaching hospitals, also, the present status accorded to the specialist in anæsthetics shows too little recognition of his responsibility and of his special training and experience. 4. The developments of modern surgery are such as to require the services of the properly trained and fully responsible anæsthetist, and it is felt that neither in respect of status nor remuneration do the present conditions give recognition and encouragement to good and sustained work. For the making of a good anæsthetist, natural aptitude, proper study, and prolonged hospital experience are all necessary, and unless those who devote themselves to the subject can look forward to reasonable prospects, the progress of the science and practice of anæsthesia must suffer. The Society recognises that any attempt to lay down rigid rules and scales of remuneration is not in accordance with the spirit of the profession. The individual specialist in anæsthetics must charge for his services in accordance with his own standing. It was hoped, however, that publication of the views of the Society may be of value in bringing before the profession the unsatisfactory nature of the present position.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. A. C. Bean has been placed on Retd. List with the rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Capt. W. Fotheringham retires receiving a gratuity.
Lt. P. L. C. Carrier to be Capt.
Temp. Capt. R. B. Bryan relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Majs. J. V. Bates (late R.A.M.C.) and G. M. Miller (late R.A.M.C.) to be Capts. and relinquish their rank of Maj.
Capt. W. L. M. Gabriel (late R.A.M.C., S.R.) to be Capt.
Capt. H. W. Bruce resigns his commn. and is granted the rank of Lt.-Col.
Capt. C. A. Sampson relinquishes his commn. and retains the rank of Capt.
Capt. C. S. Wink to be Maj.
Surg.-Comdr. A. La Touche Darley, R.N. (ret.) to be Maj.
K. S. Roden to be Lt.
Capt. R. M. Handfield-Jones to be Maj.

TERRITORIAL ARMY RESERVE.

Capt. D. O. Macdonald, from General List, to be Capt.

Maj.-Gen. J. Jackson, C.I.E., I.M.S., and Col. W. H. Ogilvie, C.B., C.M.G., I.M.S., have been appointed Hon. Physicians to the King, Indian Military Forces; and Col. R. Heard, I.M.S., has been appointed Hon. Surgeon to the King, Indian Military Forces.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 13TH.

Advertisements on Medical Certificates.

Mr. BRUFORD asked the Minister of Health whether he was aware that the backs of medical certificates issued in connexion with national health insurance were used to advertise articles of diet sold by a certain company; and, in view of the undesirability that medical men should be compelled to distribute certificates bearing what might easily be misconstrued by patients as being their doctor's recommendation of particular foods or drinks, would he exclude advertisements of this type.

Similar questions on the same subject were asked by Dr. WATTS, Mr. W. ADAMSON, Dr. SALTER, and Mr. LEACH.—Mr. NEVILLE CHAMBERLAIN replied: The considerations which led the Government to sanction the printing of advertisements on the back of this form were explained by the Paymaster-General in reply to Mr. J. H. Thomas on May 16th. Representations have been received that the advertisement of foods is open to objection, and I will consult the Stationery Office as to the possibility of securing other advertisements without loss of revenue when the present contract terminates, if there should then still be room for advertisements on the forms.

Lieut.-Commander KENWORTHY asked the Minister of Health whether he would state what revenue was expected to be derived in a year by utilising the back of the medical certificates, granted in connexion with the national health insurance, for advertising purposes; particularly what revenue was derived from the advertising on the back of the special intermediate certificates form med. 40b (revised); and whether he had had any expressions of disapproval of this practice from the medical profession.—Sir W. JOYNSON-HICKS (Financial Secretary to the Treasury) replied: The revenue from advertisements on the various medical certificates is estimated at £405 per annum (including £270 per annum from form med. 40b), and this sum is one of a large number of items of receipts for advertisements on Government publications (other than the Telephone Directory), which it is hoped will amount to about £30,000 for the current financial year. The answer to the last part of the question is in the affirmative.

Small-pox in Derbyshire.

Mr. FRANK LEE asked the Minister of Health whether his attention had been drawn to an expression of opinion by the medical officer of health for Chesterfield that the outbreak of disease in Clown, Bolsover, Ilkeston, and other places in Derbyshire, of recent date, which had been notified as one of small-pox, was not due to that complaint, seeing that its effects had none of the usual characteristics of face disfigurement and that no death had occurred in consequence; and would he institute further inquiry with a view to a correct and definite diagnosis being reached.—Mr. NEVILLE CHAMBERLAIN replied: I assume that the hon. Member is referring to certain statements which appear in the annual report of the medical officer of health of Chesterfield for the year 1922. If so, I may point out that in that report the medical officer acknowledges that his view is shared by only a very small minority. As regards the second part of the question, I may say that when similar statements were made last year an expert committee was appointed by my predecessor to examine certain patients in Chesterfield and elsewhere who had been notified as suffering from small-pox. This committee arrived at the conclusion that the disease was in fact small-pox of a mild type, a conclusion which is supported by subsequent investigations undertaken by medical officers of my department.

The Labelling of Dried Milks.

Mr. HURD asked the Minister of Health whether he was aware that skimmed dried milk was now being sold in this country with no sufficient indication that it was unfit for children as is required in the case of condensed milk; and whether he would enlarge the regulations under the Milk and Dairies Act of 1922 to cover this development.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. As I have already announced, I am considering regulations to provide for the proper labelling of dried milks.

Ex-Officers and Medical Boards.

Captain O'GRADY asked the Minister of Pensions whether the medical boards for ex-officers were held at regional headquarters; whether treatment was provided by regional medical officers; and whether it was proposed to transfer the officers' awards to the regional awards sections.—Captain CRAIG replied: Medical boards for ex-officers are held at regional headquarters and other convenient centres in

the provinces. Arrangements for providing treatment for ex-officers in the provinces are made by regional medical officers. It is not proposed to transfer the officers' awards to the regional offices. The Departmental Committee over which my right hon friend presided in 1920 recommended the continuance of the centralised system of officers' awards.

National Health Insurance Act.

Mr. WILLIAM M. ADAMSON asked the Minister of Health whether he intended to renew the National Health Insurance (Prolongation of Insurance) Act for the year 1924.—Mr. NEVILLE CHAMBERLAIN replied: Yes, Sir.

Disinfectants and Venereal Disease.

Mr. PETO asked the Secretary of State for the Home Department whether his attention had been called to the Report of the Committee of Inquiry on Venereal Disease; and whether he intended to introduce legislation during the present session to give effect to their recommendation to permit properly qualified chemists to sell appropriate disinfectants.—Mr. NEVILLE CHAMBERLAIN replied: The report of this committee is under consideration, and I am not yet in a position to announce what action will be taken upon their recommendations. I may add as regards the second part of the question that I am advised that there is nothing in the existing law to prevent chemists selling disinfectants for purposes of prevention of any venereal disease so long as they are not sold accompanied by any written or printed recommendations.

Manufacture of Morphia and Heroin.

Captain JOHN HAY asked the Secretary of State for the Home Department the number of factories in Great Britain where morphia and heroin are made; the amount of these drugs manufactured last year (1922); and the quantity sent abroad.—Mr. BRIDGEMAN replied: The number of factories licensed at the present time for the manufacture of morphia and heroin is two. The amount of morphia made in 1922 was 315,342 oz., of which, however, 173,010 oz. were converted into codeine or heroin, leaving a net total of 142,332 oz. The amount exported was 115,465 oz. The amount of heroin made in 1922 was 31,673 oz., and the amount exported 25,911 oz.

Nurses' Registration.

Dr. CHAPPLE moved an humble address to His Majesty praying that the rule made by the Minister of Health on May 23rd under the Nurses' Registration Act, 1919, should be modified so as to permit of the registration of nurses who have not had hospital training, but who produce certain certificates testifying to their character, to their nursing ability, and to their having completed three years' nursing practice prior to Nov. 1st, 1919.

Lieut.-Colonel FREMANTLE said he wished to give the reason why he differed from his professional colleagues who were supporting the motion before the House. If Parliament had decided on a democratic constitution for the nursing profession and that constitution was represented by the present General Nursing Council, who had clearly declared that it was impossible for them to recognise as satisfactory such bona fide nurses as would come in after the year 1910, the House could not possibly pass the proposal before them.

Mr. NEVILLE CHAMBERLAIN (Minister of Health), who later announced that the Government whips would be taken off for the division, said that he thought that Dr. Chapple's proposal went too far, but he would be willing to accept as a fair compromise a motion in the name of Colonel Fremantle which would bring on to the register nurses who were engaged in nursing on Nov. 1st, 1919, and who were also bona fide engaged in nursing prior to Jan. 1st, 1910.

Dr. Chapple's motion was carried by 111 votes to 81, and Colonel Fremantle's address and another in the name of Major Barnett were ruled out of order in consequence.

THURSDAY, JUNE 14TH.

The Fire at the Birmingham Pensioners' Hospital.

Mr. AUSTEN CHAMBERLAIN asked the Minister of Pensions if he had any information with reference to the fire which took place on the previous day at the pensioners' hospital at Highbury, how the injured were progressing, and what provision would be made for the dependents of those who had lost their lives.—Mr. W. M. ADAMSON asked a similar question.—Major TRYON replied: I have received a full report of this distressing fatality from one of my medical officers whom I sent to Birmingham last night immediately on receipt of the news. The hospital is not one which is owned by the Ministry, but has been made available for its exclusive use by special agreement with the Birmingham Pensions Hospital Committee, which is responsible for the administration. The fire took place in an isolated open-air ward shortly after 2 o'clock yesterday afternoon. The cause of it is still quite obscure. It originated in a small room at one end of the ward and the outbreak was at once observed

by the orderly on duty who, assisted by a patient, immediately attempted to deal with it, and gave the alarm. The fire brigade arrived in about five minutes. In the meantime practically the whole staff of the hospital had arrived on the scene and, together with all patients who were fit to do so, endeavoured to put out the flames and to remove the helpless patients from the ward. The fire, however, spread rapidly, aided by the gale of wind which was blowing at the time, and even before the fire brigade had arrived the position of the patients had become a matter of the utmost difficulty and danger. The rescue work was carried out at the cost of considerable injuries to some individuals, and the behaviour of all concerned calls for the highest praise. The ward was an open-air hut of the most modern type, such as is extensively used in this and other countries for the treatment of severe and often hopeless cases of tuberculosis and other diseases requiring ample access to sun and air. It was of wooden construction on a brick foundation with a galvanised iron roof. There were two exits; one was at the end of the hut, where the fire started, and was at once rendered inaccessible. The other was an opening 9 ft. wide in one side of the hut, through which two beds could simultaneously be removed. There were thus ample opportunities for exit in any normal emergency. There were in the ward nine full water buckets and two fire extinguishers. The number of patients in the ward at the time of the outbreak was 15, of whom only three could help themselves. In addition to the two patients who unfortunately lost their lives there were two who were seriously injured. I am glad to learn from further inquiries which I made this morning that they are going on well, though not yet out of danger. Other injured patients and members of the staff are progressing satisfactorily. I wish to express my sincere sympathy with the relatives of the men who have died and with those who have been injured. The House may rest assured that the claims of the dependents of those who have lost their lives will be generously and sympathetically dealt with. On the question raised by the hon. Member for Cannock, full inquiry will be made into all the circumstances, including the suitability of this type of building.

Pensions Nursing Service.

Mr. MURNIN asked the Minister of Pensions what were the numbers and grades of the Ministry nursing service employed at headquarters; what were their duties; and whether he would consider transferring these duties to the regional commissioners of medical services and the medical superintendents of Ministry institutions.—Major TRYON replied: The only members of the Ministry nursing service employed at headquarters are the matron-in-chief and the principal matron, who are engaged in the general supervision and co-ordination of the work of the whole nursing service. I am not prepared to accept the suggestion in the last part of the question, which I do not consider would be in the interests of either economy or efficiency.

Shepherd's Bush Orthopædic Hospital.

Major COHEN asked the Minister of Pensions whether the Orthopædic Hospital at Ducane-road, Shepherd's Bush, had to be closed down at the end of the year; and, if so, what steps the Ministry were taking to provide for the present patients the specialist treatment needed by them.—Major TRYON replied: The lease on which these premises are held expires at the end of the present year, and arrangements are being made for the accommodation of the patients by an extension of the facilities at Roehampton.

Panel Treatment for Service Pensioners.

Mr. EDWARDS asked the Minister of Pensions whether he was aware that ex-Service men who applied for treatment were told that treatment was necessary but that their panel doctor would prescribe for them; and would he make arrangements so that when treatment was necessary it could be given under the pensions scheme, and that it should carry with it treatment allowance.—Major TRYON replied: Under the terms of the Royal Warrant my department is only empowered to defray the expenses in respect of treatment which is not otherwise provided. Whether treatment is provided at the direct cost of the Ministry or whether it is provided by the man's insurance practitioner, treatment allowances are paid if it is certified that the man, as a consequence of having to undergo treatment, will, during treatment, be unable to work at a remunerative occupation.

India and Opium Control.

Mr. PONSONBY asked the Under-Secretary of State for India whether the representatives of the Government of India on the Advisory Committee on Opium of the League of Nations made any reservations in accepting the American principles with regard to the interpretation of The Hague Opium Convention; and, if so, for what reason did the Government of India adopt a different attitude from that of the other delegates, who accepted the principles without reservation.—Earl WINTERTON replied: The hon. Member is mistaken in supposing that the American principles met

with unanimous acceptance from all countries except the Indian Government. Certain other countries made a reservation regarding the use of opium prepared for smoking. The Indian reservation was to the effect that the use of raw opium according to the established practice in India, and its production for such use, are not illegitimate under the Convention. The reason for this is the fact that insistence on a medical prescription to enable raw opium to be used for medical or quasi-medical purposes would be impracticable in India.

Lead Poisoning among Painters and Plumbers.

Mr. ARTHUR GREENWOOD asked the Secretary of State for the Home Department whether he was aware that of the eight cases of lead poisoning among house painters and plumbers which came to the knowledge of the Home Office during April six were fatal; and whether, in view of these facts, he would urge upon the Government the importance of ratifying the white lead convention as recommended by the Norman Committee.—Mr. BRIDGEMAN replied: The question of ratifying the convention is receiving careful consideration.

Terms and Duties of Panel Doctors.

Sir KINGSLEY WOOD asked the Prime Minister whether before any revision was made in the terms and duties of doctors on the panel lists an opportunity would be afforded to the House of discussing the matter.—Lord E. PERCY replied: The Government cannot at this stage undertake that, when a settlement has been reached with the doctors, an opportunity will be given for the discussion of the new agreement before it comes into operation, but even if no express legislation is necessary Parliament will have an early opportunity for reviewing the terms of the agreement next session on the Vote on Account.

Cannock Chase Pensions Hospital.

Mr. ADAMSON asked the Minister of Pensions whether it had actually been decided to close the pensions hospital on Cannock Chase, and, if so, whether he would state the reasons for adopting this policy in view of the large expenditure incurred in building and equipment.—Major TRYON replied: Owing to the decreasing requirements for hospital accommodation in the Midlands arrangements have been made for the gradual closing of this hospital.

FRIDAY, JUNE 15TH.

Children in Workhouses.

Mr. CHARLES ROBERTS asked the Minister of Health the number of children over 3 years of age who on Jan. 1st, 1923, were being maintained in workhouses, workhouse infirmaries, sick wards of workhouses, wards for mental deficient, and other wards respectively.—Mr. NEVILLE CHAMBERLAIN replied: The figures are as follows:—

	Suffering from sickness, accident, or bodily infirmity.	Suffering from mental infirmity.	Not suffering from sickness, accident, or bodily or mental infirmity.	Total children between 3 and 16 in specified institutions.
Separate institutions for sick persons suffering from disease of body or mind—				
Infirmaries	4,753	157	28	4,938
Institutions solely for mental cases	—	1,118	—	1,118
Institutions administered under the Poor-law Institutions Order, 1913—				
Sick wards	2,293	157	29	2,479
Separate wards of children	—	—	1,466	1,466
Other wards	62	399	1,096	3,023
	7,108	1,831	2,619	11,558

The above figures do not include (a) children in separate establishments for children, or (b) children in institutions not provided by Poor-law authorities.

Small-pox in Gloucestershire.

Sir WALTER PRESTON asked the Minister of Health whether the official employed by the Gloucester medical officer to distemper houses where small-pox had occurred had himself contracted the disease, and when this official was last vaccinated.—Mr. NEVILLE CHAMBERLAIN replied: I have made inquiries of the local authority and am informed that no official employed to distemper houses where small-pox has recently occurred in Gloucester has since contracted the disease.

Sir WALTER PRESTON asked the Minister of Health how many cases of small-pox there had been in Gloucestershire

in January, February, March, April, and May of this year, and whether any special steps had been taken to cope with the disease in Gloucestershire.—Mr. NEVILLE CHAMBERLAIN replied: The numbers of cases of small-pox which have been notified in Gloucestershire, including the city of Gloucester, during these months have been as follows: January, nil; February, nil; March, 8; April, 25; and May, 31. There is, however, evidence to show that many cases have occurred in the city of Gloucester during the past two months which have not been recognised as small-pox by the medical officer of health and have not been notified. Special visits have been paid by medical officers of my department to the districts in which the disease has occurred, in order to assist and advise the local authorities and their officers. In the case of Gloucester, two of these medical officers have at the request of the local authority assisted in the diagnosis of cases and in the organisation of suitable measures to meet the emergency, and these officers discovered a number of cases which had been incorrectly diagnosed or overlooked. I have since caused a communication to be sent to the local authority recommending the several special steps which should be taken to deal with the outbreak, and I understand that effect is being given to these recommendations.

MONDAY, JUNE 18TH.

Notification of Tuberculosis in Cattle.

Mr. ADAMS asked the Minister of Agriculture whether he would re-introduce the Tuberculosis Order of 1914, or one having similar effect, in which tuberculosis in cattle was made a notifiable disease; and whether he would promote a measure to compel all county authorities and the larger cities or combinations of smaller authorities to appoint whole-time veterinary officers, and to compel the application of regular veterinary inspection of cattle, particularly dairy herds, throughout the country, such officers to be also responsible for the inspection of meat in the districts concerned, and if need be to set up veterinary departments for this purpose, as in certain of the larger local authorities of the kingdom.—Sir R. SANDERS replied: Unless and until I am assured that a majority of local authorities, including counties and cities, are in favour of the re-introduction of the Tuberculosis Order of 1914, I do not see my way to re-issue this Order in view of the very considerable expenditure involved not only to my department but also from local funds. With regard to the second part of the question, I would remind the hon. Member that Section 1 of the Milk and Dairies (Amendment) Act, 1922, deferred until Sept. 1st, 1925, the operation of Section 10 of the Milk and Dairies (Consolidation) Act, 1915, which contemplated the appointment of veterinary inspectors by local authorities for purposes similar to those suggested in the question.

Nurses' Registration in Scotland.

Dr. CHAPPLE asked the Under Secretary to the Scottish Board of Health whether existing nurses practising in Scotland would be eligible to take advantage of the decision of this House with regard to nurses' registration on June 13th.—Captain ELLIOT replied: The decision referred to does not apply to the rules of the General Nursing Council for Scotland. So far as the Scottish register is concerned, therefore, the answer is in the negative. As regards the position of nurses practising in Scotland in relation to the English register the matter is one for the General Nursing Council for England and Wales.

TUESDAY, JUNE 19TH.

Small-pox and Official Reports.

Mr. BROMFIELD asked the Minister of Health whether he would direct medical officers of health to record in their future annual reports the number of cases of small-pox and other infectious diseases notified from families living in houses or tenements containing one room, two rooms, three rooms, four rooms, and five or more rooms, respectively.—Mr. NEVILLE CHAMBERLAIN replied: I will consider this suggestion in connexion with the preparation of the next circular on the subject of the annual reports of medical officers of health.

PRESENTATION TO A MEDICAL MAN.—On June 11th, in the town hall at Wallasey, Dr. Bouverie McDonald, first Member of Parliament for Wallasey when it became a Parliamentary borough, was presented with his portrait in oils, which will be hung in the civic gallery. The portrait has been painted by Mr. J. A. A. Berrie, A.R.C.A., and the presentation was made by Mr. J. T. Chester, the first mayor. Mr. W. H. Robinson, the Charter Mayor, who presided, said the presentation was made the more pleasant because all sections of political opinion in the borough were associated with it. Dr. McDonald, who was elected in 1918 but did not stand at the last election, has taken a keen interest in the various philanthropic and social efforts of the borough. He has served on the Cheshire County Council and is on the Commission of Peace for the county.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.

THURSDAY, June 28th: at 4.30 p.m.

Paper to be read:—Prof. V. H. Blackman, A. T. Legg, and F. G. Gregory: The Effect of a Direct Electric Current of very Low Intensity on the Rate of Growth of the Coleoptile of Barley.

Papers to be read in title only:—Miss R. M. Tupper-Carey and Prof. J. H. Priestley: The Composition of the Cell Wall at the Apical Meristem of Stem and Root. (Communicated by Dr. F. F. Blackman.) L. J. Harris: The Titration of Amino- and Carboxyl-groups in Amino-acids, Polypeptides, &c. (Communicated by Prof. F. G. Hopkins.) Dr. M. S. Pembrey, N. W. MacKeith, W. R. Spurrell, E. C. Warner, and H. J. Westlake: Observations on the Adjustment of the Human Body to Muscular Work. F. A. E. Crew: Studies in Intersexuality. II. Sex-reversal in the Fowl. (Communicated by Prof. R. C. Punnett.) Prof. W. Finkler: Analytical Studies on the Factors causing the Sexual Display in the Mountain Newt (*Triton alpestris*). (Communicated by Prof. E. W. MacBride.) G. A. Schott: On the Scattering of X and γ Rays by Rings of Electrons: the Effect of Damping of the Incident Radiation. Major P. A. MacMahon: On a Class of Transcendents of which the Bessel Functions are a Particular Case. L. C. Martin: The Photometric Matching Field. (Communicated by Prof. H. L. Callendar.) G. P. Thomson: Test of a Theory of Radiation. (Communicated by Sir Joseph Thomson.) A. L. Hughes, and P. Lowe: Intensities in the Helium Spectrum. (Communicated by Prof. H. A. Wilson.) A. A. Dee: The Effect of Quenching from above the Carbide Transition Temperature upon the Magnetism of Steel. (Communicated by Prof. S. W. J. Smith.) T. S. P. Strangeways and H. E. H. Oakley: The Immediate Changes observed in Tissue Cells after Exposure to Soft X Rays while Growing "in Vitro." (Communicated by W. B. Hardy.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETING OF SECTIONS.

Monday, June 25th.

ODONTOLOGY: at 8 p.m.

Casual Communications:

Mr. L. E. Claremont: Case of Fibro-cystic Disease of the Lower Jaw.

Prof. Hopewell-Smith: Two Odontomes.

Paper:

Prof. Hopewell-Smith: Some Observations on the Histology and Pathology of the Dental Pulp.

Wednesday, June 27th.

SURGERY: at 5.30 p.m.

Discussion:

To be opened by Dr. William J. Mayo (Rochester, U.S.A.) on the Surgery of the Hepatic and Common Bile-ducts. Sir Berkeley Moynihan, Mr. James Sherrin, Mr. G. Grey Turner, and Mr. A. J. Walton will also speak.

Thursday, June 28th.

UROLOGY: at 8.30 p.m.

Paper:

Prof. C. G. Cumston (Geneva): The Diagnostic Value of Albuminuria in Chronic Nephritis.

Exhibition of Clinical and Pathological Specimens:

Mr. Kidd will show Candle removed from the Bladder of a Young Male Adult.

Members wishing to show cases or specimens are requested to notify the hon. secretaries.

Friday and Saturday, June 29th and 30th.

OTOLOGY.

Summer Meeting at Cambridge, at Gonville and Caius College (by kind permission of the Master and Fellows).

The meeting will be of a physiological character and will be devoted to the Labyrinth. Dr. de Kleijn (Utrecht) will describe some of the work associated with his name and that of Prof. Magnus. Other papers will be read and demonstrations given.

(For details see special circular.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE POST-GRADUATE LECTURES, 1, Wimpole-street, W.

FRIDAY, June 29th.—5.30 p.m., Sir Henry Gauvain: Heliotherapy with Special Relation to its Use in Surgical Tuberculosis.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, June 25th.—10 a.m., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 3 p.m., Dr. Simson: Diseases of Women.

TUESDAY.—10 a.m., Mr. Steadman: Dental Dept. 10.30 a.m., Dr. Paterson: Medical Wards. 2.30 p.m., Dr. Pritchard: Medical Wards.

WEDNESDAY.—10 a.m., Dr. Saunders: Medical Diseases of Children. 11 a.m., Mr. Simson: Gynaecological Demonstration. 12.15 p.m., Dr. Burnford: Medical Pathology. 3 p.m., Dr. Pernet: Skin Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
 FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 11 A.M., Dr. McDougal: Electrical Dept. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.
 SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
 Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham, S.W.
 THURSDAY, June 28th.—4.30 P.M., Mr. H. D. Gillies: Some Applications of Plastic Surgery in Civil Life.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.
 Demonstration of Clinical Cases at 3.30 P.M.

MONDAY, June 25th.—Medical: Dr. J. Browning Alexander. TUESDAY.—Surgical (3 P.M.): Mr. Howell Evans.

WEDNESDAY.—Eye Cases: Mr. Norman B. B. Fleming.

THURSDAY.—Surgical: Mr. H. W. Carson.

FRIDAY.—Diseases of Children: Dr. C. E. Sundell.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, June 25th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., X Ray Demonstration: Dr. Russell Reynolds.

TUESDAY, June 26th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Tumours Causing Compression Paraplegia: Mr. Armour.

THURSDAY, June 28th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Syringomyelia: Dr. Grainger Stewart.

FRIDAY, June 29th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Demonstration of Fraenkel's Exercises in Exercise Room.

COURSE OF LECTURES ON NEURO-PATHOLOGY.

MONDAY, June 25th.—12 noon, Syphilis of the Nervous System: Dr. J. Godwin Greenfield.

A COURSE OF 12 LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on TUESDAYS and FRIDAYS if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

WEDNESDAY, June 27th.—4.15 P.M., Dr. W. M. Feldman: The Physiology of the Infant.

THURSDAY.—4.15 P.M., Mr. G. E. Vilvandre: The Stomach from the Radiologist's Standpoint.

FRIDAY.—4.15 P.M., Mr. G. E. Neligan: Hydronephrosis and Diverticula of the Bladder.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, June 28th.—4 P.M., Dr. Cockayne: Tuberculous Mediastinal Glands.

INFANTS HOSPITAL, Vincent-square, S.W. 1.

TUESDAY, June 26th.—8.45 P.M., Mr. H. Tyrrell Gray: Pyloric Stenosis.

THURSDAY.—8.45 P.M., Dr. D. Paterson: The Treatment of Disorders of Digestion in Infants.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, June 28th.—5 P.M., Mr. A. W. Bourne: Anaesthetics in Labour.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

MONDAY, June 25th.—At Hereford, Prof. Edgeworth: Inter-relations of Internal Secretion Glands.

Appointments.

CALLANDER, L. D., M.D. Edin., has been appointed Visiting Surgeon, Poor-law Infirmary, Doncaster.

FORREST, A. W., M.D., Ch.B. Edin., D.P.H., Medical Officer of Health for Wandsworth.

GASPEY, E. T. D., M.D. Brux., M.R.C.S., L.R.C.P., Assistant Tuberculosis Officer and Resident Medical Officer, the Sanatorium, South Shields.

SMITH, G. F. R., M.B., B.S. Lond., M.D. Liverp., Lecturer on Dental Anaesthetics in the University of Liverpool.

YATES, IRENE, M.D. Lond., M.R.C.P. Lond., Assistant Physician, Elizabeth Garrett Anderson Hospital.

Chelsea Hospital for Women: GALLETLY, A., M.B., Ch.B., M.C., Registrar; JONES, A. D., M.R.C.S., L.R.C.P., House Surgeon.

Surgeons under the Factory and Workshop Acts: HALSTEAD, W. W., M.R.C.S., L.R.C.P. Lond. (Totter); OWEN, R., M.D., C.M. Edin. (Bangor); and INGLIS, T., F.R.C.P. Edin. (Ryde).

Vacancies.

For further information refer to the advertisement columns.

Barbados General Hospital.—Jun. Res. S. £250.

Birmingham and Midland Hospital for Skin and Urinary Diseases, John Bright-street, Birmingham.—Asst. Radiologist.

Brighouse Borough, &c.—M.O. and School M.O., &c. £750.

Chesterfield and North Derbyshire Royal Hospital.—Cas. O. and Orthopaedic H.S. £170.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250.

Durham County Council Maternity and Child Welfare.—Asst. Welfare M.O. £600.

East African Medical Service.—M.O. £600.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Afternoon Cas. O. £120, Part-time Path. £400.

Elizabeth Garrett Anderson Hospital, 144, Euston-road.—Jun. Asst. Pathologist. £100.

Godalming, Surrey, King George V. Sanatorium.—Jun. Asst. M.O. £422.

Grosvenor Hospital for Women, Vincent-square, S.W.—Hon. Reg. King's College Hospital Medical School, Denmark Hill, S.E.—Director of Dental Studies. £400.

Lancashire County Mental Hospital, Winwick, Warrington.—Locum Tenens. 7 guineas weekly.

Leamington Spa, Warneford, Leamington, and South Warwickshire General Hospital.—Res. H.P. £150.

Leicester City Mental Hospital, Humberstone.—Third Asst. M.O. and Clin. Path. £350.

Leicester Royal Infirmary.—H.S. £150.

Liverpool Royal Children's Hospital.—Res. M.O. £150.

Macclesfield General Infirmary.—Second H.S. £150.

Manchester Northern Hospital for Women and Children.—H.S. £200.

Margate, Royal Sea Bathing Hospital.—Res. S. £200.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Asst. in Electric Dept.

North Riding of Yorkshire County Council Education Committee.—Asst. Sch. M.O. £500.

Nottingham County Sanatorium.—Asst. Res. M.O. £375.

Plymouth, South Devon and East Cornwall Hospital.—H.P. £100.

Poplar Borough.—Dist. M.O. for Old Ford Med. Dist. £200.

Portsmouth Workhouse Infirmary, &c.—Med. Supt. £850. Also First Asst. M.O. and Second Asst. M.O. £350 and £300 respectively.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Two Asst. Res. M.O.'s. £80.

Queen Mary's Hospital for the East End, E.—Cas. O. £150. Also Hon. M.O. for Radio-Electro-Therapeutic Dept.

Royal Naval Medical Service.—Surgeon-Lieutenants.

Sedburgh School, Yorkshire.—M.O.

Sheffield City Education Committee.—Asst. School M.O. £500.

Shrewsbury, Royal Salop Infirmary.—H.P. £160.

Southampton County Borough.—Asst. M.O.H. £500.

South London Hospital for Women, Clapham Common, S.W.—Clin. Asst. £1 ls. per attendance.

South Shields, Ingham Infirmary.—Jun. H.S. £150.

Sunderland, Children's Hospital.—Jun. Res. M.O. £100.

Sunderland Royal Infirmary.—H.S. £160.

University College Hospital, Gower-street, W.C.—Asst. for Ear, Nose, and Throat Dept.

Weaverham, Cheshire, Hefferston Sanatorium.—Res. M.O. £600.

West African Medical Service.—M.O. £660.

Wolverhampton and Staffordshire General Hospital.—Res. Surg. O. £250.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Chirnside, Berwickshire; Stourbridge, Worcestershire; Bridgend, Glamorganshire.

Births, Marriages, and Deaths.

BIRTHS.

BADENOCH.—On June 14th, at Grange Park-road, Leyton, the wife of Dr. William M. Badenoch, of a daughter.

POWER.—On June 12th, at a nursing home, Worcester, the wife of Squadron Leader D'Arcy Power, M.C., R.A.F. Medical Service, of a son.

PRINGLE.—On June 11th, at Withington-road, Manchester, the wife of Dr. Pringle, of a son.

ROLLESTON.—On June 13th, at Upper Richmond-road, S.W., the wife of Dr. J. D. Rolleston, of a daughter.

MARRIAGES.

ROBERTS—JAMESON.—On June 9th, at St. Saviour's Ballater, Dr. Douglas Roberts to Rosabel Seymour, daughter of the late Dr. A. Seymour Jameson, and of Mrs. Jameson, of Aberdeen.

DEATHS.

FOX.—On June 13th, suddenly, from heart failure, Hugh Clayton Fox, F.R.C.S.I., M.R.C.S., of New Cavendish-street.

McDONNELL.—On June 14th, Dr. Alexander McDonnell, 39, Stamford-hill, N. 16, passed peacefully to rest, in a nursing home, after operation.

THOMAS.—On June 13th, at Lydney, Gloucestershire, Cyril Nelson Thomas, B.A., M.B., B.Ch., aged 57.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

PUERPERAL INSANITY.*

BY SIR ROBERT ARMSTRONG-JONES, M.D. LOND.,
D.Sc., F.R.C.P.,

LORD CHANCELLOR'S VISITOR IN LUNACY; FORMERLY LECTURER
ON MENTAL DISEASES, ST. BARTHOLOMEW'S HOSPITAL, AND
EXAMINER IN THE UNIVERSITY OF LONDON.

THE classification of puerperal insanity into that of (a) pregnancy, (b) puerperal, and (c) lactation has the merit of convenience: cases occur in the rough proportion of two, four, and three respectively. My own figures gave as the frequency of insanity with childbirth the approximate ratio (for London) of one case in every 1100 births, although some authorities have quoted a much higher ratio, varying from 1 in 400 to 1 in 700 births. Even if I take my own figures of only one case in 1100 births, the fact that an average of about 880,000 infants are born every year in England and Wales shows that about 800 mothers become victims to insanity each year at this period, which is a high toll taken of pregnant women.

Mental Changes, Normal and Abnormal.

Those who have studied the mental changes which occur under normal circumstances during a natural pregnancy must realise that in persons of a highly susceptible disposition—viz., those that are of the quick, nervous, and sanguine temperament, these changes are apt to be very decided and to become exaggerated. The ordinary digestive troubles, the various forms of neuralgia, the occasional insomnia, the feeling of weight and dizziness are apt to develop into more than the ordinary irritability and restlessness. They sometimes proceed to fractiousness, excitement, or extreme despondency, ending in a complete mental breakdown; the normal affections may turn into suspicion and hatred, the reproductive functions experience a reversal, and the ordinary maternal instincts become so perverted that they are a real and a grave danger to both mother and child.

It is an elementary experience in psychology that the feelings and the emotions govern our daily lives. They are the elementary excitations to voluntary action. They so completely dominate our normal conduct that when disturbed they become potent factors in the causation of insanity. During normal pregnancy the emotions are apt to be somewhat intensified, but under abnormal conditions they may become so exaggerated that insanity results, and of the so-called "ætiological factors," that described as "continuous mental stress," is ascertained to be one of its chief causes. Therefore in first pregnancies, and especially in the case of illegitimate births, we should expect to find insanity to be not infrequent. The moral factors of shame, disgrace, and the resentment that one has been greatly wronged are forms of mental stress experienced in illegitimacy; 12 per cent. of my cases were single women and in the single women the majority of the cases of insanity occurred during their pregnancy, fewer after childbirth, and fewest during lactation, the comparatively slighter incidence during lactation being doubtless due to the fact that few of the single women were allowed to nurse their own infants.

In the general population, the ratio of illegitimate births to legitimate is only 4 to 6 per cent., so it is very evident that illegitimacy, and the emotional stress associated with such a pregnancy, tend to supply one of the chief factors—viz., worry, in the determination of insanity among single women. Of first pregnancies, 78 per cent. were in single women and only 25 per cent. in married women, the fear of the ordeal is thus a totally different affair mentally to the single as compared to the married. In a third of all first pregnancies the symptoms of insanity appeared within six weeks after the confinement. The age of greatest incidence for mental breakdown in my cases was between 25 and 30. I may add, in passing, that one of my patients had suffered from an attack of insanity at the birth of each of 12 children, and in another after each of nine confinements; both cases became subject to incurable insanity at the climacteric.

Onset and Characteristics.

The symptoms of insanity in puerperal cases almost invariably begin with loss of sleep and, as in all other forms of mental disturbance, this is the most frequent and distressing of all the symptoms. It is a bad omen that must be combated at all cost. Following loss of sleep is a delirium which comes and goes, the patient gets confused on occasions, she seems to get "brain-weary," the stimulus of a voluntary

effort is maintained only for a brief interval, coherence can only be sustained for a very short period, then she begins to ramble, and be discursive, to be anxious about trifles, and to show restlessness. There is, with this stage, a dry and coated tongue, the lips and teeth have sordes, the urine is scanty and concentrated, and the bowels are constipated, showing there is defective elimination and that some toxin is infecting the patient. There is often a raised temperature and an offensive discharge pointing to the retention of some clot or membrane either in the uterus, the cervix, or the vagina; in some cases, also, toxic products are found in the urine, for I have known albumin to occur when not expected.

The insanity associated with the puerperal period appears to be often of a special kind, so much so that a "nosological entity" may be recognised. When a case of confinement begins with sleeplessness, and this is followed by a feverish and anxious restlessness, a busy and silly concern about trivial details; when there is a too ready response to outward impressions and there is a pointless, baseless chatter, there is a great danger of puerperal delirium, which may soon pass into mania, with delusions of a hallucinatory character, primarily visual, then auditory and not infrequently olfactory. In this mania there is often a marked religious exaltation, associated with erotic tendencies, prurient talk, shouting and singing. Improper suggestions are made, and these unpleasant features appear in women of unblemished character. There is often a suspicion of the husband and a distrust of those who are dearest. These symptoms of gibberish nonsense and immodest chatter are, I think, peculiar to puerperal insanity. They are as characteristic of it as depression and reserve are of the lactational form.

One of the great dangers in puerperal mania is the impulsive and unexpected conduct of the sufferer, resulting sometimes in tragic catastrophe to herself or in some serious harm to the infant. Such patients often take a violent dislike to the husband which is also extended to the offspring. Such "suicidal" tendencies affected nearly one-half of the cases that were under my care, chiefly in the insanity occurring during pregnancy, whereas the antipathy to the child occurred during late lactation.

Special Precautions in Nursing.

It will be the first aim of the nurse to avoid the stigma of certification; she will try her best to keep the patient in her own home and not have her certified.

There is a Bill now before Parliament to postpone certification and make it legal for a patient suffering from a definite attack of insanity to be cared for in an institution without certification. If a mother is certified as insane after the birth of her baby, even when she has got well and has resumed her place in the family life, she will be reminded at each successive pregnancy that she was insane with a former baby, and this worry will help—if anything can—to precipitate another mental breakdown. The certificate of insanity will also inevitably affect the future of her children and will cause a prejudice against them. Moreover, the stigma will excite a fear that her children may at some future date also require certification. A person who has been once certified and has recovered may feel that if a little more patience had been exercised by the doctor and the nurses, she might have been spared the loss of her freedom and all that this entails. It is wise, therefore, to do everything one can to carry out home treatment, but violence or excitement may make this very difficult. Violence must never be met with restraint on the part of the nurse; the patient should not be thwarted or held down, and no restraint of any kind should be practised in a private house. It is possible to do without it. At Claybury for a period of over ten years, with experience of more than 10,000 cases, some of the most acute types, restraint was never once used to control a violent patient. It is almost unbelievable that if a patient is allowed to move about and gesticulate and demonstrate without restraint or obstruction she (or he) will invariably soon settle down quietly. When patients are turned out into the gardens and grounds after a few somersaults and songs, the sensorimotor disturbances cease, and the realisation by the patient that she is no longer in the "lime-light" will bring about the cessation of all former excitement. It is therefore essential that toleration and perseverance should be regarded as essential qualities for the nurse in the successful treatment of this phase of purposeless excitement.

The risk of suicide must, however, always be borne in mind; the fire must be guarded; all medicines, lotions, and drugs must be kept from the patient's reach and sight; all sharp instruments such as knives, scissors, and razors must be removed; the key must be taken from the lock in the door to prevent her locking herself in; the windows must be blocked to prevent their being thrown open and so to suggest a precipitation; the patient's room should, if possible, be on the ground floor. It should be as free from useless furniture as can be managed, there should be no

* Abstracted from a lecture entitled the Nature of Puerperal Insanity and a Few Remarks on How to Nurse a Case, delivered before the Association of Inspectors of Midwives on May 8th.

pictures, the wallpaper must not be too glaring in colour or pronounced in pattern, and the room should be large and airy. Impulsive behaviour towards the infant is a form of excitement very prevalent with puerperal cases, and the child must be kept apart. These are the special considerations of the environment, but it is imperative that the same precautions should be observed out-of-doors also, as the patient should be out as much as possible, and similar precautions hold good. Watchfulness on the part of the nurse is the secret of safety, but the nurse's attention must not be too direct or obtrusive, and at least one nurse by day and one by night (with the necessary relief) must be provided for all cases. Of all illnesses a mental one is the most expensive; but in acute insanity, in the early stages, it pays to spend freely upon the patient's welfare and treatment.

As to the patient herself special attention has to be given to the condition of the breasts, which may need strapping and support, and in particular to cleanliness, and to the aseptic treatment of discharges. A hot douche of plain boiled water cooled to 110° or a mild antiseptic added to it will sometimes bring down the temperature almost at once. The cleanliness of the patient must always be the nurse's first consideration and a hot bath may be the only method of securing this, as she may resent other interference. Special attention must be given to the state of the bladder, as in delirious conditions there may be a distension and even an overflow. The urine must also be examined microscopically, as well as bacteriologically, by the doctor, and the nurse must place specimens before him either naturally passed or withdrawn by catheter. I have known unsuspected albumin to be present, as also pus, and the *Bacillus coli*, and these associated with very great discomfort and restlessness. Constipation is the bane of cases of delirium and this must be avoided by the use of calomel, as it will probably be impossible to use the enema syringe. Sleep is the chief aim of the nurse in mental cases, and for this the "long immersion" bath will prove most helpful, and it will also assist in cleansing any foul discharges. Sleep can often be helped by the administration of a small quantity of alcohol with liquid nourishment, such as a little brandy or dry sherry, or even a tumblerful of stout with a teaspoonful of malt extract in it. I have seen mild suggestion and stroking the hand or forehead soothe to sleep some very restless cases. Of all the difficulties in nursing puerperal cases, feeding is one of the most imperative to carry out properly. Liquid food must be administered during every quiet interval, and enforced alimentation or compulsory super-alimentation must be had resort to, though the nurse must not use any form of mechanical feeding, this being left to the doctor; uniform kindness and a firm determination will often overcome the patient's resistance to taking food. In these states of toxæmia, unless feeding is efficiently carried out, the patient may die before restoration can be effected.

Conclusion.

An old physician has wisely said that no medicinal agents can directly relieve a disordered mind. This can only be effected by controlling the disordered body with which the disordered mind is associated, and great experience and much investigation are necessary to ascertain this disorder and to discriminate it from other disorders of the body. The morbid and effete material which has been taken up into the circulation during the period of early uterine involution must be eliminated through the venous, the lymphatic, and the excretory organs of which the skin, the lungs, the kidneys, and the bowels are the chief. If this kind of nursing care can be secured and maintained for a few weeks, it will probably be rewarded by a complete convalescence, and the tact, the watchfulness, the patience, and sympathy of the nurse will result in at least 70 per cent. of these cases getting well before the expiration of three months. There is no form of insanity that so well repays the nurse for her extreme self-denial, devotion, and skill as that associated with the puerperal state, nor is any form more rapidly fatal if not properly treated.

HEALTH CONDITIONS IN TRINIDAD.¹

THE population of Trinidad, together with that of the neighbouring island of Tobago, as taken at the census in April, 1921, was 365,913, and was estimated to be 366,760 at the middle of that year. The birth-rate was 31.7 (as stated on p. 3 of the report, not 31.1, as stated on p. 4), and the death-rate is returned as 24.05 per 1000, as compared with 22.15 for the quinquennium, 1916-20; but the ratio for 1921 is acknowledged to be not correct (owing to difference between the estimated population for 1920 and the census population of 1921), and the actual number of deaths (8824) was 502 less than in 1920.² The infantile mortality ratio (139 per 1000 births), though showing an

¹ Report for 1921 of Medical Inspector of Health, Trinidad. Govt. Printing Office, Port of Spain. 1922.

² (Page 1.) On page 9 the difference appears as 414.

improvement on that of the previous year (174), and of the quinquennium, 1915-19 (147), is still high; in the town of San Fernando it was 243 per 1000, in Port of Spain 174, in the rural districts as a whole 129. Enteric fever showed a great improvement; the cases numbered 820 and the deaths 240, compared with 1198 and 295 in 1920; 521 of the cases and 161 of the deaths occurred in the three districts of Port of Spain, Tacarigua, and St. Joseph. Dr. J. R. Dickson, medical inspector of health, who forwards this report, considered that contact, direct or indirect, was the chief mode of spread; inoculation of contacts and education in personal cleanliness were the measures of control chiefly carried out (and presumably local sanitary, or insanitary, conditions dealt with as required).

Pulmonary tuberculosis was notified in 442 cases, and caused 473 deaths (1.28 per 1000) during the year; in 1920 there had been 552 notifications of this disease. "The preponderance of pulmonary cases emphasises the fact that infection is very largely due to personal contact and environment, and indicates that preventive measures should be largely educational, in the direction of early detection of cases, personal cleanliness, improvement of dwellings, and generally of home conditions." Of the 442 cases notified in 1921, 206 dwelt in Port of Spain; and of the 473 deaths 203 occurred in the same urban district. Pneumonia accounted for 470 deaths during the year (p. 7), giving a ratio of 1.29 per 1000 (not 1.0 per 1000 as stated on p. 3); of the 470 deaths, 174 occurred in the two urban districts of San Fernando and Port of Spain. Anti-malarial measures are being carried out in various parts of the island; venereal clinics have been established in Port of Spain and San Fernando; and the intensive curative and educational campaign against ankylostomiasis of the Rockefeller International Board is being continued.

ST. CHAD'S HOSPITAL FOR PAYING PATIENTS, BIRMINGHAM.

THE report of the hospital committee for the year ending March 31st, 1923, records a fall in the number of admissions (752 against 833 in 1921-22), due to the general industrial depression prevailing throughout the year. "Even the low inclusive fees charged have been beyond the means of many who in more prosperous times would gladly have availed themselves of the advantages" offered by the hospital. The area from which patients were received is wide, ranging from Redcar and Whitehaven to Weymouth; almost all patients paid an inclusive fee for accommodation and treatment, which was about 50 per cent. lower than the cost of similar private treatment elsewhere. There are now 32 specialists on the staff of the hospital; the opportunities for training of nurses are exceptionally good, the practical knowledge obtained in the wards being supplemented by systematic lectures by a sister tutor and by the resident medical officer and members of the medical staff. Great interest in the hospital has been manifested by other centres, and information has been sought not only by authorities from London, Glasgow, and other cities, but by the Director-General of Health, Wellington, New Zealand. The committee have endeavoured to make St. Chad's fulfil as completely as possible the conditions laid down by the Advisory Committee to the Minister of Health as desirable in a hospital for paying patients; it has now been made possible for patients to make direct applications to this hospital for admission and treatment. Application must be made to the house governor, who is empowered to assess the amount of fees payable according to the nature of the treatment required and the financial circumstances of the patient. "In the interest of the patient it is strongly recommended that a letter of introduction from his or her doctor should be presented at the time of application, or the name of the doctor given."

AN IMPROVED FIRELIGHTER.

WE have received from "Certo" Limited, 42, High-street, Hampton Wick, Middlesex, specimens of a patent firelighter which consists of slips of an inflammable material 5 in. by 1 in. pivoted together at the centre so that the slips can be spread out in the shape of a star which is then placed in the grate between layers of coal. No paper or wood is required, and, if the fire is carefully laid, the result is good. When the firelighter is in its closed condition a hundred of them only occupy a space of 10 in. by 6 in. by 6 in., so that the arrangement is economical of storage room. The price is 6d. a packet of ten firelighters.

Messrs. Burroughs Wellcome and Co. have acquired a site at 9/11, East Forty-first-street, New York, almost opposite their old offices, and have erected upon it a 12-storey building in the Gothic style. The lower part of this building is now occupied by the firm as its general offices for the U.S.A., the ground floor being utilised for the display of fine chemicals and medical equipments.

An Address

ON THE

SURGERY OF THE HEPATIC AND COMMON BILE-DUCTS.

Read before the Surgical Section of the Royal Society of Medicine on June 27th, 1923,

BY WILLIAM J. MAYO, M.D.,
ROCHESTER, MINNESOTA.

To the clear brain and clever hands of Lawson Tait, the father of modern abdominal surgery, who early made excursions into this field of biliary surgery, we owe much, but to the Leeds school, more than to all other influences, we owe the knowledge and methods which have made the upper abdomen, from a surgical standpoint, one of the best understood and most satisfactory regions of the human body. Robson's publications and his untiring work as an investigating surgeon made him the leader for his generation in surgery of the biliary tract, and in Moynihan, his brilliant successor, we recognise the ablest exponent of the principles and practice of surgery in this field. Moynihan's clearness of presentation and lucidity of explanation, in conjunction with unequalled technical ability, have given him a name and fame which are the pride of the English-speaking people.

THE MATERIAL OF THE MAYO CLINIC.

The President of the Surgical Section of the Royal Society of Medicine has asked me to open the discussion of the subject of surgery of the biliary passages from the standpoint of the surgeon and to deal with the art, rather than the theory and the science of surgery. Perhaps I can best accomplish this by discussing the material from the clinic with which I am connected, outlining the viewpoint of the various surgeons working in the clinic, and the methods of treatment which they have found most effective. I shall discuss the common duct and the main hepatic duct because the pathologic processes with which the surgeon is concerned in this special field must be treated as a whole.

In the period from Dec. 31st, 1890, to Dec. 31st, 1922, there were 16,980 operations performed on the biliary tract for all conditions, acute, chronic, and malignant, by the surgeons on the general staff of the clinic, with an average mortality of 2.6 per cent. Of these operations, 1920 were on the common and hepatic ducts with an average mortality of 7.8 per cent. In the ten years from 1910 to 1920 the average mortality for operations on the common and hepatic ducts was 6.8 per cent. In 1921 the mortality for operation on the common and hepatic ducts was 5.6 per cent. In 1922, by reason of better pre-operative preparation of patients, the mortality dropped to 3.8 per cent. for operations on the common and hepatic ducts, and to 1.6 per cent. for 142 cholecystectomies.

All patients dying in the hospital following operation, without regard to the length of time thereafter, or the immediate cause of death, were classified as having died from the operation. It may seem somewhat severe to classify patients as having died from operation, who, when operated on, had chronic nephritis, hepatic insufficiency from biliary cirrhosis, and secondary cardio-renal disturbance, the result of months of cholæmia and duct infection, and patients who had died in the hospital some weeks after operation from causes not connected with it. However, without an arbitrary standard of classification, it is difficult to secure comparable statistical data from different hospitals. Perhaps, too, there is a certain stimulation in holding ourselves to a high standard of responsibility.

Satisfactory improvement, so far as mortality is concerned, is manifest by these data. Improvement has been greater than would be apparent by a study

of mortality alone, because of constantly increasing knowledge and improvement in technique more and more severe cases have been undertaken, and operations carried out successfully which, in the earlier days, were not attempted.

THREE FUNDAMENTAL PRINCIPLES.

Certain fundamental principles which greatly affect the welfare of surgical patients must be evaluated. They concern: (1) mortality from the operation, (2) benefit from the operation, and (3) disability following the operation.

Mortality from the Operation.—On one occasion, to the great delight of an American audience, Moynihan said: "Statistics can be made to tell anything, even the truth." This is especially true of mortality percentages following surgical operations. The pride of the operator and his statistical skill in honestly juggling percentages make most astonishing apparent differences in statistics which are nearly identical. For instance, the early transference of the dangerously ill patient to the medical side of the hospital, because of a medical complication is helpful from the standpoint of surgical statistics. If operations, rather than cases, are counted, and a number of operations are performed on the same patient, a small series of cases may make a large series of operations. Mortality estimated by cases is high, estimated by the number of operations low, although the number of deaths would be the same. Again, a slight operation which does not cure will be a test in a bad case. If the patient does not react well, the curative procedure entailing a major operative risk may not be undertaken; consequently the patient is not given the chance for cure which a primary radical operation would have given.

Benefit from Operation.—We study surgical tragedies and endeavour in every way to hold operative mortality at the lowest point, but the mere fact that a patient recovers from an operation is not in itself sufficient. He was alive when the operation started and if he does not receive sufficient benefit to warrant the risk of life, the pain and suffering from the operation itself, the expense, and the loss of time, he has just cause for dissatisfaction. On the other hand, if a more radical operation would have resulted in correspondingly greater benefit, an increase of primary risk might have been justified.

Disability following Operation.—The question of post-operative disability is important. A surgical procedure should be planned so that the patient, with the least possible risk and loss of time, will receive the greatest possible benefit. To-day industry is on a full-time basis and every unnecessary day that the patient is disabled is an economic loss. To perform several operations when one would suffice, and thus attain an apparent, but not a true reduction in mortality, to use a type of incision not strictly indicated for the work at hand, or to use unnecessary drainage which will confine the patient to bed longer, or leave him with a greater liability to hernia, is unjust, and whether the patient is paying his own way, or is the occupant of a charity bed in the hospital, his own money or that of the hospital donors is being wasted. This economic loss is illustrated by a comparison, at ten-year intervals, of the hospital morbidity following operations on the biliary tract. The methods in use to-day, as compared with methods used ten years ago, save for each patient operated on in the clinic ten days of hospital time, or 36 years of the life-time of one person each year. I will outline briefly the general plan of procedure that is used in our clinic in operations on the hepatic and common ducts.

GENERAL PLAN OF PROCEDURE.

Incision.—The incision used in the majority of operations on the biliary apparatus has been that introduced by Bevan in 1908, slightly modified. It is started high in the angle between the costal cartilage and the right side of the sternal notch and extends down not more than 1.5 or 2 cm. from the middle line to a point opposite the umbilicus. The method of

c c

McArthur in leaving undivided the posterior aponeurosis, the peritoneum, and the nerves in the lower third of the incision is followed, because these are sufficiently mobile to be drawn down readily by a retractor. I have not known hernia to follow in the part of the incision so protected. The upper and lower angles of the incision are made from 4 to 5 cm. longer through the fat and subcutaneous tissues, which have no retentive power, than through the external aponeurosis and the muscle, which enables good exposure with less muscle damage. This type of incision permits ready exploration of the entire abdomen and, if cholecystectomy or appendectomy is necessary, the gall-bladder and usually the appendix can be brought into view. A middle-line incision is very effective, especially if splenectomy is necessary at the same time. Occasionally the transverse incision is used. It is understood, of course, that in the individual case any type of incision for the better exposure of the operative field will be adopted.

Exposure of the Common Duct.—The exposure of the common duct is the most important step in the operation. Since that part of the common duct, which is visible when the liver is retracted, passes more or less to the left, the inexperienced operator may forget that when the duct passes behind the duodenum it turns sharply downward and becomes parallel to the long axis of the body, close to the middle line. It has been shown that in about two-thirds of the cases the common duct runs through the head of the pancreas, and in about one-third behind it, which determines the effect of coincident pancreatitis on bile drainage in gall-stone disease and other infections of the bile-ducts. The gall-bladder and cystic duct are the ready guides to the common duct, but it should not be forgotten that the cystic duct is not at the bottom of the gall-bladder, but to the inner side, and that the pelvis of the gall-bladder may overlap the cystic duct and cover the preduodenal common duct. The pelvis of the gall-bladder must be carefully separated from the common duct and drawn upward until the cystic duct is exposed. While ordinarily the cystic duct passes directly to the common duct, not infrequently it opens on the posterior or upper surface of the common duct, or runs parallel with it for a distance, possibly even to the duodenum. Failure to recognise such anomalies may lead to accidental injury to the common duct. A second not infrequent source of accidental injury, especially to the hepatic duct in the operation of cholecystectomy, lies in the failure carefully to secure the cystic artery, which usually lies behind the cystic duct, close to the liver in the gall-bladder notch. When cut, the cystic artery promptly reacts and gives rise to a sharp hæmorrhage. If the operator uses rat-tooth forceps in this bloody angle he is likely to bite out a portion of the hepatic duct, an injury which, if not promptly repaired, leads to permanent obstruction. When a cystic artery escapes, a little basket should be made by a non-biting curved forceps, grasping the tissue round the bleeding-point until the artery can be lifted away from the hepatic duct in a manner to expose the vessel safely for ligation. As Brewer points out, the cystic artery occasionally comes from the superior pancreatico-duodenal, and runs up the face of the exposed common duct; if it is cut a very troublesome hæmorrhage results.

SECONDARY OPERATIONS.

Secondary operation on the common and hepatic ducts for the removal of stones, especially if the gall-bladder has been removed at the first operation, may be most difficult, particularly if dense adhesions bind the area in a confused mat, and a state of hepatitis or biliary cirrhosis makes the liver bleed at a touch. Ordinarily, in these cases, the common duct runs in the lower margin of the gastro-hepatic omentum with the portal vein and hepatic artery behind and above, but the portal vein may be displaced and opened accidentally. However, if the opening in the portal vein is grasped with the thumb and finger, the hæmorrhage can be easily controlled temporarily and several light, curved compression forceps without teeth slipped

under the fingers to hold the injured vein until it can be sutured with light catgut, as it is held and covered with fragments of the gastro-hepatic omentum. In secondary operations on the common and hepatic ducts following cholecystectomy, if the surgeon finds the place in the gall-bladder notch from which the cystic duct has been removed, and follows this close to the liver, aspirating frequently with a glass syringe and a long fine needle until bile is discovered, he may save time over quicker methods which may lead to troublesome accidents.

So far as the removal of stones from the exposed duct is concerned, it is not difficult ordinarily. But it is sometimes difficult to determine whether all the stones have been removed from the duct. Even when the duct is sufficiently large to admit the finger, for careful examination of its interior, stones may sometimes be left because they are high in the liver ducts where they cannot be detected, or they may be hidden in diverticula and the instruments pass by them into the duodenum. For this reason, after all the detected stones have been removed, an opening should be made by gentle instrumentation through the papilla into the duodenum, sufficient to permit undetected stones to pass into the duodenum later in any case. If the common duct approaches 1 cm. in diameter it should be explored, because stones, especially of the Fenger ball-valve type, may be present with very little physical evidence; in 30 per cent. of patients operated on for stones in the common duct, little or no jaundice exists at the time of operation. The importance of removing all stones from the duct cannot be over-estimated. In nearly one-third of the deaths which followed operation on the common duct for stone in our series, post mortem revealed that all stones had not been removed. Since post-mortem examinations are made on more than 90 per cent. of patients who die in the hospital, this checking up has been of very great importance in adding to our knowledge, although often humiliating to the surgeon. Perhaps some of the stones which are supposed to have re-formed in the common duct are left-overs.

THE QUESTION OF BILE DRAINAGE.

Duct Drainage after Operation.—Davis, by animal experimentation, was the first to call attention to the fact that bile drainage following operation on the common duct is necessary in the jaundiced patient when marked duct infection exists. Kehrer, whose large experience and high mortality following operations on the biliary tract give him an unusual opportunity for post-mortem examination, especially insists on hepatic duct drainage. In a series of cases of this particular description it was found wise to use hepatic duct drainage by the Robson catheter method. Following explorations for removal of quiescent or latent stones from the common duct, hepatic duct drainage is unnecessary. The duct is closed with interrupted catgut sutures, and a soft rubber drain is carried down into the pouch, the early description of which by the distinguished surgeon of Newcastle-upon-Tyne has given it the name in the States of "Morison's pouch." If there is much oozing of blood, especially from lacerations of the liver, it may be wise to carry a strip of salvaged iodoform gauze over the injured surface of the liver where it readily becomes adherent, and as the portal blood pressure is but 30 mm. will usually check oozing from slighter injuries which do not require suture.

Restoration of Normal Bile Drainage.—In my experience, next to gall-stones in the hepatic and common ducts, operative injuries during cholecystectomy are the most common cause for operations on the common duct. The most serious and difficult operations are those whose purpose is the restoration of totally interrupted biliary connexion between the liver and the intestinal tract. When the common or hepatic duct has been injured and the fact has been recognised at the time, failure successfully to repair the injured duct has not occurred in a single instance. The tissues are normally pliable and movable to a considerable degree, and if as much as 2 cm. of the duct is lost, the

severed ends can be drawn together by end-to-end suture and union takes place. If an anemic jaundiced patient is operated on weeks or months after the injury the story is very different.

In a period of 22 years, 104 patients were operated on for restoration of function between the hepatic and common duct and the duodenum, with a hospital mortality of 15. The late mortality in all the years since the operation was 19. Twelve of these late deaths were due to progressive biliary cirrhosis, one to carcinoma of the pancreas, 11 years after operation, and four to other causes not connected with the operation. Of the remaining 90 patients the present condition of 63 is known; 5 are well, seven in fair health, and 11 continue to have more or less symptoms. A study of the operative methods employed in these cases, from the standpoint of ultimate results, indicates that in any case in which a piece of the duct has been accidentally removed, and the injury not discovered and repaired at the time, thus necessitating secondary reconstruction, direct union between the stump of the hepatic duct and the duodenum is the best operation. One patient on whom I performed this operation, in 1903, as remained well, raised a number of children, and as survived typhoid fever and pneumonia. The ability of others of these patients to withstand the vicissitudes of life has been equally well demonstrated. The best results were obtained when a muco-mucous union between the proximal end of the hepatic duct and the duodenum could be effected. The method of Walton was used in two of the successful cases. A rubber tube connexion after the Sullivan method, which was popularised by Wilms, gave good temporary results in a few very difficult cases, but eventually results were unsatisfactory. The use of a T tube did not prove favourable, as its removal had a tendency to disturb the line of union. If a rubber tube is used, it is fastened in position with catgut and allowed to pass out spontaneously through the intestine, as it did eventually in our cases. When it is possible to bring the distal end of the common duct in apposition with the proximal portion by suture the use of a piece of catheter with a cuff on the end inserted into the hepatic duct and the distal end passed through the common duct into the duodenum as advised by McArthur gives excellent function. While the results of this series of cases have not been all that could be desired, they are not wholly unsatisfactory when the desperate pre-operative condition of many of the patients is considered.

Malignant Disease of the Common Duct.

In a number of instances sections of the common duct have been removed for cancer without a single ultimate cure, although in several instances the primary results were very satisfactory, one patient living for three years. Cholecysto-gastrostomy in malignant obstructions, whether in the head of the pancreas or in the common duct, has proved a remarkably satisfactory operation. For benign disease cholecysto-duodenostomy is preferable theoretically and it is usually practised in the clinic. In several doubtful cases which proved to be benign, cholecysto-gastrostomy has given good symptomatic results for many years.

PRE-OPERATIVE PREPARATION OF CHOLÆMIC PATIENTS.

Of the causes of death after operation, hæmorrhage and renal insufficiency, and infections of the bile-ducts are the most common. These conditions are directly related to the existing chronic obstructive jaundice, cholecystitis, biliary cirrhosis, dehydration, and chronic under-nourishment. Walters reviewed the post-mortem records, for a five-year period, of patients who died following operation on the biliary tract, and demonstrated that in 58 per cent. of the patients with jaundice, who died within the first week after operation, there was more or less blood in the abdominal cavity, usually the result of oozing from slight injuries to the liver. Of itself, the hæmorrhage was not always

sufficient to cause death, but it was a contributing factor. Walters then made a direct comparison between the cases with jaundice in which cholecystectomy had been performed and those in which cholecystostomy had been performed in conjunction with operations on the common duct. He found that in the cases of jaundice with infected ducts the death-rate following cholecystectomy was much greater than that following cholecystostomy. In jaundiced patients in poor condition, unless definitely indicated, a cholecystectomy is not added to the risk of the operation on the common duct, because of the danger to the liver which adds to the possibility of slow post-operative oozing.

Dehydration.—As these patients are dehydrated, and usually unable to take much nourishment, an attempt is made before operation to introduce a quantity of water into the system to aid renal elimination. As a rule it is difficult to accomplish this by mouth; it is best accomplished by proctoclysis, or subcutaneously. Walters found that the jaundiced patients who died following operation regularly had terminal nephritis with gradually increasing blood-urea before death, and that the result could be predicted as the blood-urea rose day by day.

Hepatic Insufficiency.—A third factor of importance in these cases is hepatic insufficiency, which runs parallel with renal insufficiency. In the presence of hepatic insufficiency, the blood-sugar may appear to be at the normal level when it is not truly so, because of the concentrated state of the blood from dehydration. Mann, in the clinic laboratories, has shown that if the liver is removed from a dog the animal goes into collapse in a few hours and dies. If, however, the dog just before death is given glucose in saline intravenously he is relieved at once, regains his strength rapidly, and in a few minutes appears to be restored. In such experiments, by continuing the glucose, dogs were kept alive for from 24 to 36 hours. Therefore, in the presence of hepatic insufficiency, 5 per cent. of glucose in plain water by rectum, or 3 per cent. in sodium chloride solution, is given subcutaneously. For subcutaneous administration the glucose must be sterile and chemically pure, to obviate late abscess formation. If the patient is very sensitive small amounts of procaine added to the glucose in sodium chloride solution, as recommended by Bartlett, will make it possible to give the infusion painlessly.

Hæmorrhage.—In order to check hæmorrhage, chloride of calcium, intravenously, has proved effective, and in certain cases blood transfusion is a remedy of remarkable efficiency. The blood contains prothrombin, which starts the clot, and antithrombin, which tends to prevent the prothrombin from clotting. When the tissues are cut, thromboplastin, which escapes from the tissues, unites with the antithrombin, and the prothrombin clots. The blood and tissues of the patient with hæmophilia are lacking in these three factors, and therefore his blood does not clot. Hæmophilia is transmitted through the female to the male; no thoroughly authenticated case of hæmophilia in the female has been noted. The remedy is blood transfusion; there is no cure. The second constituent of the blood-clot is the blood platelets. In purpura hæmorrhagica the blood platelets are deficient. The third constituent of the normal blood-clot is calcium. In the jaundiced patient the blood calcium is exhausted by combination with bile-pigments and acids, and this exhaustion may take place as early as three weeks after the onset of the jaundice, or, in some instances, calcium exhaustion may be delayed for many months. Failure of normal blood-clotting in the jaundiced patient is a specific indication of deprivation of blood calcium. Wright was the first to point this out. Cammidge and Robson added to the knowledge of the subject both experimentally and clinically. The difficulty was that the amount of calcium taken up either by the stomach or the rectum was always small, and in some patients was not observed. It remained for Lee and Vincent to give chloride of calcium in a 10 per cent. aqueous solution intravenously

with striking results. Sometimes following a single injection a clotting time even of 30 minutes would be reduced to nearly normal. Three injections on successive days usually are sufficient to restore blood-clotting to normal. The estimation of the blood calcium is made by a simple method described by Sanford. When the administration of calcium fails to reduce the clotting time to normal, blood transfusion will usually make a temporary reduction in the clotting time, sufficient for an operation to be performed.

The gradual development of these excellent methods of blood rehabilitation in the clinic was begun by Hallenbeck; later, Bell advanced the work, and it was carried to the present stage of efficiency by Walters. The careful preoperative management of jaundiced patients has greatly reduced the mortality from operations. In two years not a single patient so prepared died from hæmorrhage following the operation.

UNEXPECTED DEATH, ESPECIALLY IN CHILDREN,

WITH COMMENTS ON STATUS LYMPHATICUS.*

By ERNEST GLYNN, F.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF LIVERPOOL;
PATHOLOGICAL SUPERINTENDENT, ROYAL LIVERPOOL
CHILDREN'S HOSPITAL;

AND

ROBERT CRAIG DUN, F.R.C.S. ENG.,
SURGEON, ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

(From the Thompson Yates Laboratory, University
of Liverpool.)

THE expert pathologist after making a post-mortem examination upon a case of unexpected death, especially in an infant, is often forced to admit that he really does not know the cause of death. The organs may appear normal—macroscopically at any rate; or if lesions are present they may not seem sufficient to be fatal. On account of the youth of the patient he is unable to take refuge in the diagnosis of "fatty heart"; instead he is tempted by that of "status lymphaticus." In such circumstances, however, there is always the possibility of an acute or of a terminal infection, as illustrated by the following six examples.

Six Examples.

CASE 1. Early Tuberculosis; Death from Terminal Infection with *Streptococcus faecalis*.—Male, aged 9 months, admitted to the Royal Liverpool Children's Hospital under the care of one of us (R. C. D.) with prolapsed rectum of six weeks' duration and bronchitis. Past history good. The buttocks were strapped, and the prolapse was cured. No temperature during first 12 days in hospital; 24 hours before death the father was told that the child was going on well. Next day, however, at 10 A.M., he became very ill, the tongue and mouth were dry, the temperature rose to 102° F., and he died at 5 P.M. after seven hours' illness. The father was so perturbed by the unexpected death that he threatened proceedings against the hospital.

Post Mortem.—The examination was made 20 hours later. A caseous patch of tubercle the size of a cob-nut present in middle lobe of right lung, and enlarged caseous glands around right bronchus. A few miliary tubercles present in both lungs, and on peritoneal surface of liver and spleen, but none were found in kidneys. Lower end of ileum contained two early minute tuberculous ulcers; peritoneal coat unaffected. Some mesenteric glands were enlarged and beginning to caseate. Tonsils appeared normal. Brain appeared normal.

It was difficult to explain the slight but sudden rise of temperature and especially why the child died. Death was not due to miliary tuberculosis, because there was no clinical evidence of it, and the tubercles

found were too few; this was subsequently confirmed by sections of the liver and kidney, which showed no tubercles. There was no clinical nor macroscopic evidence of meningitis; this was subsequently confirmed by sections of the brain around the Sylvian fissure. The brain of a tuberculous case with slight symptoms of meningitis may appear normal macroscopically, yet microscopic examination of the Sylvian fissure region may reveal inflammatory exudate and tubercle bacilli. This has been observed twice at the Liverpool Royal Infirmary, on a female, aged 20, and on a male, aged 15. Cultures from the heart-blood and the spleen both grew a streptococcus in pure culture. It gave the reactions of *Streptococcus faecalis* (Hohlman's classification) when tested in lactose, salicin, and mannite broth; the hæmolytic reaction when tested against suspended human red blood corpuscles was "indifferent."

Conclusion.—The child died of a terminal infection with *Streptococcus faecalis*, which almost certainly entered the blood-stream from the minute ulcers in the ileum. Had it lived, death would probably have occurred a few months later from acute miliary tuberculosis.

CASE 2. Tenotomy; Death apparently from Status Lymphaticus, really from Acute Encephalitis.—Male, aged 6 months, admitted on Oct. 6th to the hospital with right congenital talipes equino-varus, under the care of one of us (R. C. D.). Child very well nourished, appeared quite healthy; bowels regular, temperature normal. On the 7th at 3.30 P.M. subcutaneous tenotomy of the tendo Achillis and wrenching of the right foot were performed under ether. The child appeared perfectly well after the operation. Next morning (the 8th) the temperature rose for the first time, reaching 99.6°, but was normal at night. On the 9th, at 7 A.M., the child became blue; at 9 A.M. it vomited some apparently blood-stained material and passed a loose green stool. The temperature was subnormal, but the pulse 120 and respiration 60. At 2 P.M. the temperature was 102° and respirations 60. The child died suddenly at 8.30 P.M. after about 13 hours' illness. There were neither convulsions nor nystagmus. A catheter specimen of urine was normal.

Post Mortem.—The examination was made 16 hours after death. Thymus appeared much enlarged, its maximum length being 8½ c.mm., its weight 27.4 g. Spleen weight 15.5 g., normal. The stomach, which was beginning to autolyse, appeared normal, but contained an ounce of blood-stained fluid. Contents of duodenum bile-stained. Mesenteric glands appeared about normal size, but there was slight enlargement of the Peyer's patches and solitary follicles of the intestine. Liver rather soft—microscopically it showed a moderate amount of congestion and fatty infiltration. Kidneys normal—confirmed by microscopic examination. Brain and other organs appeared normal.

It was difficult to account for death; but a certificate of status lymphaticus was given, as the thymus weighed 27.4 g., though the spleen was not enlarged and there was little other evidence of lymphoid hyperplasia. The weight of the normal male thymus at 6 months is stated to be between 2.25 and 13.5 g., and its length at 7 to 9 months to average 5.9 cm (Vierordt).⁴ Nevertheless this diagnosis was felt to be unsatisfactory, so cultures were made from the spleen, but only *B. coli* grew. This organism was probably a post-mortem invader, especially as no bacteria were found in sections of the kidney, liver, or brain.

Since the cause of death was still unexplained the brain, preserved in formalin, was sent to Dr. G. Watson, of the County Mental Hospital, Rainhill. He was especially requested to examine the medulla. Dr. Watson reported as follows:—

"Thirty-two blocks were cut and examined. The principal lesion was a vascular wall infiltration—the so-called 'perivascular infiltration.' It was most marked in the medulla and adjacent spinal cord, the pons, and crura cerebri particularly in the grey matter. It especially affected the veins, and consisted chiefly of lymphocytoid cells with few developing plasma cells forming a cuff or sleeve which was often very large. The vessels were congested with hæmorrhages, thromboses, and necrotic foci were absent. There were also numerous islets of lymphocytoid and other cells in the tissues—apparently apart from the vessel. Many of the anterior horn cells of the cord were rather severely degenerated and so were groups of nerve cells in the

* Read at the Liverpool Medical Institution, April, 1923.

pons, medulla, and crura, but the cells of the oculo-motor nerves were practically normal. In the cerebral and cerebellar hemispheres, including the basal ganglia, there was little change beyond a few minute inflammatory foci in the grey matter, some acute oedema of the nerve cells, and a slight infiltration of the meninges. No organisms of any kind were found."

Conclusion.—The child therefore died of acute meningo-encephalo-mylitis, which proved rapidly fatal, partly because it attacked the medulla. The disease resembled early encephalitis lethargica. The absence of ophthalmoplegia is consistent with the absence of lesions in the oculo-motor nuclei. The absence of lethargy is possibly connected with the absence of ophthalmoplegia. It has been suggested that the two are usually associated, because "the nucleus of the third nerve and certain of its emergent fibres bear intimate relation to the afferent fibres streaming towards the thalamic region, neopallium, &c." (Reports on Public Health).³

CASE 3. Fulminating Pneumococcal Pneumonia without Consolidation.—Male, aged 15, lived in a Liverpool industrial school. On March 1st, 1910, he was working from 7 A.M. to 5 A.M.; after breakfast, at 9.30 A.M., the governor noticed him looking blue and cold, but he stated, "I feel all right, Sir." He was, however, sent to the kitchen fire to warm himself. At 11 A.M. he still maintained he was quite well, but at 2 P.M. complained of headache, vomited, and was put to bed: the temperature was 102°. Later he became delirious and comatose. Death occurred at 4 P.M. after 1½ hours' illness.

Post Mortem.—Carried out 12 hours after death in the institution. The body was that of a well-nourished boy. Nothing abnormal was detected, except slight congestion of the brain, redness and enlargement of the bronchial lymphatic glands, and redness of the trachea, which contained some rothy blood-stained mucus. There was also a moderate amount of oedema and congestion of the lungs, but no trace of consolidation either to the naked eye or on palpation. The pleura contained a few petechial hæmorrhages.

The dramatic nature of the illness and the enlargement of the bronchial glands suggested the possibility of pneumonic plague. Smears were therefore made from the lung juice and examined microscopically. They swarmed with Gram-positive capsulated diplococci resembling pneumococci. A mouse was injected with the blood from the lung and died two days later from typical pneumococcal septicæmia. Sections showed acute bronchitis, also acute congestion of the lungs with a trace of inflammatory exudate and a light deposit of blood pigment. Clusters of pneumococci were demonstrated in the bronchi and lung alveoli. There was also advanced parenchymatous degeneration of the kidney and extensive deposits of blood pigment.

CASE 4. Fulminating Pneumococcal Pneumonia without Consolidation.—Male, aged 15, living in the same industrial school. On Nov. 15th, 1912, he received a slight kick on the leg while playing football. He was kept in bed, a mentation applied, and seen at mid-day by a doctor, who found nothing wrong except a slight bruise. Shortly afterwards he complained of headache; at 2 P.M. he vomited and the temperature rose to 101°. Later convulsions occurred, and he died seven hours after the acute symptoms developed.

Post Mortem.—The post-mortem and microscopical appearances were almost exactly similar to those of the last case. Pneumococci were demonstrated in the lung juice and confirmed by inoculation into mice. No pneumococci grew from the cerebro-spinal fluid; sections of the cerebral cortex revealed no meningitis.

These two are the most striking examples of 15 cases of acute pneumonia with four deaths which occurred in two small epidemics in the industrial school in 1910 and 1912 (Glynn,¹ 1913). In one of the remaining two deaths—that of another boy of 15, where the illness lasted much longer, namely, about 30 hours—the thymus was greatly enlarged. It weighed 56 g., the middle measured from above downwards 5 cm., and the right lobe 8½ cm. McGowan and McNeil² (1913) independently described similar but larger series of cases in an industrial school near Edinburgh.

Two cases of fulminating pneumococcal pneumonia in adults which are remarkably similar to the last will next be described; they also illustrate the occasional

difficulties of making a post-mortem diagnosis when death occurs unexpectedly.

CASE 5.—Female, aged 18, was always healthy and worked as usual on the morning of May 25th, 1918. In the afternoon she complained of headache; about 8 o'clock she vomited. Next morning at 9 she was found dead on the sofa, still fully dressed.

Post Mortem.—The examination was made 36 hours after death. The lungs were definitely congested but not consolidated. The bronchial glands were enlarged and dark red, again suggesting the possibility of pneumonic plague. The thymus was "considerably enlarged"; the record of weight has unfortunately been mislaid. As the diagnosis of status lymphaticus was not satisfactory, films were made from the lungs and pneumococci found. Two mice inoculated with the lung and gland juice respectively died in 24 hours of pneumococcal septicæmia. Sections of the lung showed intense congestion, some of the lung alveoli being filled with red blood corpuscles. Fibrin was practically absent, and leucocytes were absent. Enormous clusters of pneumococci were present. The kidney showed profound cloudy swelling, many of the tubules being completely degenerated, but unlike the preceding cases, this case showed no blood pigment.

CASE 6.—An army sergeant, in civil life a cotton merchant, aged 42, returned home on leave in December, 1918. His health was good, but after a week he complained of a slight sore throat. A doctor friend examined him one afternoon, found his temperature was normal, and prescribed some lozenges. On the same evening upon going to bed he vomited once, but otherwise had a good night. At 9.15 next morning his wife brought him breakfast, but he vomited again and could not eat it. She went out of the room for a few minutes, leaving him sitting up in bed. On her return he was unconscious and died almost at once.

Post Mortem.—The examination was made two days after death. The trachea was dark crimson and both lungs were partially consolidated, especially the posterior part of the right upper lobe: they weighed 1 lb. 10 oz. and 1 lb. 8 oz. respectively. Spleen, weighing 13 oz., difficult. Brain slightly oedematous. Heart, weighing 13 oz., normal. A persistent thymus found, divided into two lobes, the right measuring from above downwards 6.2 cm., the left 5.5 cm.; transverse diameter 3 cm. Microscopical sections cut through two portions of thymus showed that about three-quarters of it was fat, but one-quarter contained lymphoid tissue and Hassel's corpuscles. Lymphoid follicles at root of tongue enlarged, but no enlargement of Peyer's patches nor of the solitary follicles in the intestine. Microscopical films from bronchus showed many organisms—viz., Gram-positive diplococci resembling pneumococci, streptococci, and Gram-negative bacilli resembling *B. influenzae*. The lung juice and spleen juice showed organisms resembling pneumococci. Two mice were injected with the lung juice; both died from typical pneumococcal septicæmia. Cultures of the lung juice grew *Staphylococcus albus*, a *Streptococcus longus*, and pneumococci. No influenza bacilli were cultivated on bullock's blood medium. Sections of two portions of the lung showed intense congestion; groups of alveoli contained serous exudate and a few red blood corpuscles. There was a very extensive deposit of blood pigment, not only in the lung, but also in catarrhal cells and blood vessels. Pneumococci were demonstrated in clusters, but no influenza bacilli.

Comments.

It is necessary to refer again to status lymphaticus. One of the first difficulties in diagnosing this condition is the contradictory statements regarding the weight and size of the normal thymus gland at varying ages. Data concerning these points are at present being collected by a committee of the Pathological Society on behalf of the Medical Research Council; the secretary, Prof. E. Emrys-Roberts, of Cardiff, would welcome information regarding the size of the thymus "in all subjects of 15 years or over, and in all cases of sudden death (anaesthesia, injuries, burns, &c.) in apparently healthy persons of any age."

In our opinion there was undoubted thymus enlargement in Case 2, the infant dying after tenotomy, and in Case 3, an industrial school-boy, aged 15, dying of fulminating pneumococcal pneumonia. It is noteworthy that McGowan and McNeil² also observed a similar thymus enlargement in "several" of their pneumonia autopsies. It is also noteworthy that the thymus was persistent in Case 5, the girl of 18, and in Case 6 the man of 42 dying of fulminating pneumonia.

[†] It is interesting that all five patients—including the third industrial school boy—dying of fulminating pneumococcal pneumonia, vomited.

The present state of our knowledge suggests that persons with enlarged or persistent thymus are in a state of unstable equilibrium and easily killed by a shock or an infection.

In conclusion, it is obviously a grave error to attribute an otherwise unexplained death solely to status lymphaticus, without making a bacteriological examination—supplemented if necessary by a microscopic examination of the brain. When deaths like these are the subject of a coroner's inquest such an investigation is essential. Yet how often is it done? The coroner and his officials are apt to think that the doctor who has "looked inside" the body of a person probably dead from natural causes, but who next recommends *further investigation* to ascertain the cause of death, is either deliberately wasting public time and public money, or is a fool!

METASTATIC GONORRHOEA.

Being the Opening Remarks in a Discussion before the Medical Society for the Study of Venereal Diseases

BY SIR THOMAS HORDER, BART., M.D.,
F.R.C.P. LOND.,

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THE name chosen for this discussion has obvious objections, but it is difficult to find an equally trite name as a substitute. The term "metastatic gonococcus infection" is free from etymological criticism but is cumbersome. The meaning of "metastatic gonorrhoea" is at least free from ambiguity.

Anatomical Classification.

Based upon anatomical considerations gonococcus infections may be usefully divided into five categories:

- (1) *The primary focus of infection*: urethra, cervix uteri, conjunctiva, &c.
- (2) *The zone of local extension*: prostate, seminal vesicles, epididymis, endometrium, Fallopian tubes, peritoneum, &c.
- (3) *A septicæmia*—i.e., a general blood infection without focal lesions.
- (4) *A pyæmia*—i.e., a general blood infection with focal lesions.
- (5) *Focal lesions without general blood infection*—i.e., "metastatic gonorrhoea."

(1) and (2) are outside the scope of this discussion. (3) is a rare condition; the gonococcus does not tend to simple septicæmia, in this way resembling the staphylococcus group of micro-organisms to which, indeed, it properly belongs. (4) is not very uncommon; it is seen in the more severe cases of gonococcal arthritis and fibrositis, and in gonococcus endocarditis of the ulcerating or malignant kind. (5) is the group of gonococcus infections which forms the subject of our discussion proper; it belongs to the type of infective process which is conveniently termed "focal sepsis" and is very characteristic of the gonococcus.

Gonococcal Metastases.

Let us first state briefly what are the forms of metastatic gonococcal sepsis met with clinically, and then consider the mechanism of their production, their course, diagnosis, prognosis, and treatment.

1. The most common manifestation of metastatic gonorrhoea is, undoubtedly, that group of diseases termed generically *gonorrhoeal rheumatism*. This group includes arthritis, fibrositis, teno-synovitis, bursitis, myositis, and peri-neuritis. Spondylitis or arthritis of the spine is a not uncommon variety of this affection. The group will be dealt with fully by Sir William Willcox.

2. Infections of the *bones and cartilages*, apart from involvement of the joints, are rare, but they have been described; they are probably of the nature of periostitis and osteomyelitis, as in staphylococcus infections.

3. The *eye* is infected not infrequently, both in the *iris* and the *conjunctiva*. Gonococcal *iritis* is a well-known metastatic affection, tending to recurrence. It is probably the most frequent form of *iritis* next to streptococcal infection. An important feature is the long interval that may elapse between the date of the primary infection and the occurrence of the *iris* inflammation. It is much more common than syphilitic *iritis*, for which it is not infrequently mistaken. *Conjunctivitis* is usually a primary infection, but there is reason to believe that it, like *iritis*, may (rarely) be metastatic in origin.

4. The *heart*. It is highly probable that not a few cases of "simple" mitral disease owe their origin to gonococcus infection. This fact is, however, impossible of proof. Not so in "malignant" or "ulcerating" endocarditis, in a small percentage of cases of which disease it has been shown convincingly, both by blood culture during life and by post-mortem investigations, that the lesions have been due to the gonococcus. These are cases of gonococcal arterial pyæmia. The first authentic case of this kind was published in America by Thayer and Blumer in 1896. The first case in this country was described by Horder in 1904.¹

5. The *peritoneum*, as already stated, may be infected by direct extension from the primary focus. This, as might be supposed, is less uncommon in women than in men. The infection is usually local in its distribution. General peritonitis may, however, occur, and in this event the patient is almost always a female. Though sometimes difficult of proof, the assumption is usually made that the Fallopian tubes are always infected in these cases, and that the condition is never a true metastasis.

Questions of Pathogenesis.

What is the nature of the pathological process in metastatic gonorrhoea? In a good number of the joint cases, and in the cases of infective endocarditis due to the gonococcus, we are evidently dealing with a condition of pyæmia; from the blood-stream, or from the joints, or from both, the causative microbe can be isolated by careful technique in a sufficient percentage of the cases to warrant this conclusion. In the more chronic cases, and in those in which there is no evidence of a septicæmic process, we are uncertain if the symptoms are due to an actual colonisation of organisms in the affected tissue, or to the action of gonococcal toxins upon specially susceptible tissues. Knowing how elusive the gonococcus is, and how prone it is to lie hidden in the recesses of such structures as a joint or a tendon-sheath, we must not conclude that because (say) a specimen of joint puncture fluid yields no growth on even the most suitable media, the joint structures are not actually infected by the organism. Indeed, it is probable that in the majority of severe cases they are. But in other cases it is probable that the symptoms really are of the nature of an intoxication, the "focal sepsis" which gives rise to absorption of toxins being situated in one or other of those tissues referred to as within the zone of extension of the primary focus of infection.

A question of great importance in connexion with the pathogenesis of metastatic gonorrhoea is this: What organ or tissue acts as the immediate source of dissemination of the organism via the blood-stream? Is it the seminal vesicle or the prostate in the male? Is it the cervix, the endometrium, or the Fallopian tube in the female? For there seems little doubt that in the zone of local extension the spread of infection takes place via the lymphatics, whereas the metastatic foci appear as the result of an invasion of the blood-stream from one of these infected areas within the local zone.

¹ Trans. Path. Soc., vol. lviii., pt. 1.

Diagnosis.

The direct bacteriological proof that a suspected metastatic gonococcal focus of infection is actually of this nature is generally very difficult, oftentimes impossible. It is, indeed, rarely possible except in the severe cases. By direct proof I mean the isolation and identification of the infecting organism. Indirect bacteriological proof becomes, on this account, of great importance. But the serological tests of gonococcal infection are not as yet so precisely defined as to establish a good criterion for diagnosis. The agglutination method is not at present helpful, and, from the characters of the organism, the method does not seem very hopeful. The complement-fixation method, however, though for the time being it is still undergoing modification and trial, promises to be of much greater service. The recent exploitation of polyvalent antigen seems likely to reduce this method to greater uniformity of results than formerly. I am indebted to my colleague, Dr. Mervyn Gordon, for a reference to the most recent paper on this subject,² by Wilson, Forbes, and Schwartz. These authors raise two main questions: (1) Is the test specific, and (2) is the test an aid in diagnosis? The conclusions reached are (1) that the "negative results with control human sera indicate that the gonococcus complement-fixation test is specific," and (2) that it is an aid to the clinician in institutional work. Of cases in the acute and subacute stage 47 per cent. were positive, while of chronic cases 73 per cent. were positive. Of doubtful cases 60 per cent. were positive. Bearing in mind that it is in the chronic cases that we are denied the advantage of direct bacteriological proof, the smaller percentage of positive results in the acute and subacute cases is not such a material loss as might at first be thought.

Course and Prognosis.—Secondary Infections.

It is the chronicity, and the tendency to recurrences, of the gonococcal metastases that render these pathological processes so damaging and so disabling. We have no test by which we can form a judgment as to the immunity of the patient from a risk of recrudescence of his infection even many years after the last manifestation of his infection. I have seen an undoubted instance of gonococcal iritis occur 14 years after the primary infection was to all appearances "cured." No doubt instances of even longer latency will be cited.

The prevalence of secondary infections, by streptococci, staphylococci, diphtheroids, and coliform bacilli is notorious, and this tendency renders gonococcal infections all the more tedious and intractable.

Treatment.

The first principle in the treatment of metastatic gonorrhœa is drainage of the primary focus and of its zone of local extension. This involves highly specialised technique by those who are expert in genito-urinary surgery. Supplementary measures are both specific and non-specific. Of specific measures the use of gonococcus antigen is, I think, of proved value, though the best form of remedy is as yet undetermined. We shall, no doubt, hear advocates on behalf of the ordinary gonococcus vaccine, of detoxicated vaccine, and of gonococcus "immunogen" so prepared as to render the cell structure more easily digested by the tissues and containing some of the specific endotoxin in solution. It will be interesting to learn if any members of this Society have had experience of Broughton Alcock's method of using live gonococci intravenously. There appears to be no commonly adopted scheme of dosage of the ordinary killed coccus, doubtless in part due to the fact that we are dependent in most of the chronic cases upon a "stock" vaccine, and also to the fact that different strains of gonococcus used in their preparation differ widely in virulence.

Non-specific supplementary measures include all known methods of raising the general resistance of the patient. But amongst these methods no drug, so far as I know, has any special claim.

NOTES ON TREATMENT BY ELECTROLYSIS OF SOME AFFECTIONS OF THE NOSE AND EAR.

By A. R. FRIEL, M.D. DUB., F.R.C.S. IREL.

It is convenient to draw a distinction between the terms electrolysis and ionisation. The latter is specially applied to (a) the introduction into the tissues of particles called ions from a solution of a salt; (b) the exchange of ions between cells and fluids in the tissues under the action of the constant electric current. By electrolysis in this paper is meant (a) the introduction of ions into tissues from solid metals in contact with their surface or actually pushed into their substance; (b) the action on the tissues of chemical substances, such as acids or alkalis, formed at the point of contact between the tissues and the metal. With the effect due to the formation of alkali we are familiar when a sewing-needle, attached to the negative pole of a battery, is inserted into a hair follicle to loosen the hair and destroy its root.

When we desire to deposit an ion such as zinc in the substance of the tissues, and to act in the depth rather than on the surface, we use a needle or rod of the metal and plunge it right into the tissues until it reaches the exact part on which we wish to act. The zinc ion, whether derived from a solution of a salt or from a metallic rod, produces coagulation of the tissues into which it is carried by the electric current. The extent of penetration of the ion and the amount of coagulation caused depend on the strength of current used, and the time during which the current flows. There is a sharp delimitation, shown by the effect, between the tissues into which the zinc ion has penetrated and the tissues in the neighbourhood. The former being coagulated are killed, the latter are not even irritated. The effect is much more strictly delimited than when other physical or chemical agents such as heat and caustics are applied. Owing to the coagulation produced by zinc ions, hæmorrhage is avoided and the extension of sepsis is prevented through the occlusion of lymph and blood-vessels by a sterile coagulum.

Applications of Electrolysis.

Many cases of nasal obstruction are due to enlargement of the inferior turbinal. For the treatment of this Prof. Leduc recommended and practised many years ago the introduction of ions from a zinc needle. The diagram (Fig. 1) shows how this is done. The part of the needle outside the tissues as well as for 1/16 in. inside the point of entrance is coated with an insulating varnish—e.g., shellac. Where the needle passes through the nostril it is well to slip over it in addition a short piece of split rubber tubing to avoid any possible chance of leakage of current and a burn. A needle made of steel and electrolysed with zinc is easy to introduce. To it is soldered three or four feet of thin copper flex ending in a short piece of stiff wire which can be inserted into the positive terminal of the battery or rheostat. The negative electrode is applied to the arm or leg. A suitable dose is 15 ma. for 30 minutes. The current should then be reduced to zero. If an attempt is now made to pull out the needle it will be found that it is tightly held by the coagulum in the tissues; and if the attempt is persisted in considerable hæmorrhage will ensue and the good effect, due to the aseptic coagulation of the tissues in the substance of the turbinal, nullified. To loosen the needle the current should be reversed for a short time (ten minutes at ten milliampères). The development of alkali in immediate contact with the needle dissolves a thin layer of coagulum. The needle can then be withdrawn without pain or hæmorrhage. Beyond wearing a plug of cotton-wool in the nostril for an hour, no after-treatment is required. The procedure can be readily carried out under cocaine in the consulting-

² Journal of Immunology, vol. viii., No. 2, March, 1923.

room or the out-patient department. The patient has no need to lie up or stay away from work. The treatment is not nearly so severe as, either, cauterisation with the galvanocautery, as it avoids the risk of sepsis and inflammation, or, as cutting off a portion of the turbinal with scissors, with the danger of subsequent hæmorrhage. A similar procedure (Fig. 2) may be adopted for some cases of spasmodic sneezing with profuse watery discharge when the mucous membrane of the septum opposite the middle turbinal is much swollen. The zinc-coated needle is introduced into the soft tissues of the septum and a current of 10 to 15 milliamperes is passed for half an hour, followed by a reversal of the current till the needle can be easily withdrawn.

Chronic Maxillary Empyema.

In many cases the cause of chronicity is solely the irritation of septic fluid in the cavity. In these cases if the cavity is disinfected by zinc ionisation the discharge will usually cease at once. If for any reason—e.g., want of an operating theatre, or of skilled assistance to carry out the technique of ionisation—another method of treatment is necessitated, the following (Fig. 3), which has proved successful in four consecutive cases, may be adopted. The cavity is punctured with a trocar and cannula, and washed out in the usual way, and any fluid remaining in the cavity blown out with the air douche. Into the puncture hole if possible, or if not, through an adjacent area, a strong needle coated with zinc is pushed. The needle where it passes through the nostril and under the inferior turbinal is insulated with rubber tubing. It is connected with the positive terminal and the negative electrode is applied to the arm or leg. A current of 15 milliamperes is passed for three-quarters of an hour, and after a short reversal of the current the needle is withdrawn. In one of the four cases referred to the cavity was washed out once subsequently, and in one of the others two electrolytic applications were made, as the instrument used on the first occasion was not satisfactory. Otherwise the patients had no further treatment of the antrum. What advantage for the uncomplicated case does this method present as compared with one of the usual operations? It is easily carried out

under local anæsthesia with little discomfort. There is no need for the patient to remain in bed; there is no plugging of the nose, no risk of hæmorrhage, and less damage is done to the tissues.

One of the factors incidental to the operation (not to the disease) which tends to promote chronicity is avoided. In the usual intra-nasal operations there is considerable damage to the naso-antral wall. This is formed of a layer of bone with a layer of mucous membrane on each side. Following the operations, granulations are likely to form around the artificial opening. These may exude fluid which it is impossible to keep sterile, and consequently a certain amount of septic fluid may be present to act as an irritant. In the electrolytic form of treatment there is only slight trauma, and the tissues adjacent to the puncture are sealed by coagulation so that exudation is limited.

The same method of treatment may be adopted for an infected ethmoid bulla, and it will be possible here to see at a subsequent date the clean-cut opening resembling a perforation in a tympanic membrane.

Ear Conditions.

In certain cases of chronic otorrhœa in

which septic fluid is present in a situation inaccessible by ordinary means, it is an advantage, from the point of view of treatment, if a portion of the outer wall of the attic could be removed. This can readily be brought about by destruction of the tissues by electrolysis. (Fig. 4.) The strength of current which can be comfortably borne is 3–5 ma. It should be kept flowing for from half to three-quarters of an hour. Local anæsthesia with Bonain's fluid allows the necessary manipulations to be carried out with little difficulty.

For the treatment of polypi and large granulations I have found nothing so efficacious as zinc electrolysis. I have had frequent opportunities of treating such cases in children. A little cocaine and adrenalin solution is first applied. One or two dry cells furnish ample current and are convenient. An effort is made to introduce the points of the needles either through, or alongside, a polypus into its base (Fig. 5) and so to destroy its nutrition. When one examines an ear a few days subsequent to this treatment it is surprising to find the polypus gone and no sign of inflammatory

1. Introduction of zinc needle into the inferior turbinal. 2. Introduction of zinc needle into the soft tissues of septum. 3. Introduction of zinc needle into the naso-antral wall. 4. Destruction of portion of the outer wall of the attic. 5. Destruction of polypus.

reaction. After the polypus has disappeared some cases do not require zinc ionisation to cause the otorrhœa to cease. The cause of chronicity was the irritation due to the polypus and to the decomposition of its secretion.

The adoption of electrolysis, with or without subsequent ionisation, permits of an increase in the number of cases of chronic otorrhœa which can be cured without much difficulty.

TRAUMATIC ASPHYXIA.

By ALAN MONCRIEFF, M.R.C.S. ENG.,
HOUSE SURGEON, THE MIDDLESEX HOSPITAL, LONDON.

THIS somewhat rare condition has been defined as a "diffuse ecchymosis of the face and neck resulting from compression of the trunk" (Lejars¹). A case recently admitted to the Middlesex Hospital was a very good example of this condition.

A Recent Case.

CASE 1.—A male, aged 19, was lying flat on a hoist which moved up and crushed him between it and a trap-door which failed to open. He was held in this position for about 20 minutes. On admission his face and neck were much swollen and of a deep plum colour which ended at a definite line about the level of his thyroid cartilage. Subconjunctival ecchymoses were present in both eyes; the right pupil was slightly larger than the left, but both reacted to light. Some slight bleeding took place from the right ear, but there was no fracture of the base of the skull. Bruises were present over the right shoulder, the right side of the sternum, and the upper right costal cartilages. An angular deformity was present over the lower thoracic and upper lumbar vertebrae; the knee-jerks were not elicited. The patient was quite conscious but very irritable; respiration 60, hurried and difficult, pulse 132, temperature 96°F. The urine contained no abnormal constituents.

By next day the colour of the face and neck was slightly deeper, and the "collar line" was well marked; pulse 120, respirations 36, temperature 99.2°. The colour gradually faded from the face and neck, no colour changes usual in ecchymosed tissues taking place. In the conjunctiva, on the other hand, the usual colour changes appeared as in the other bruised situations. A skiagram showed several slight linear fractures of the upper end of the right humerus and of the glenoid. The spine condition was recognised as a healed Pott's disease. In about 14 days the colour of the face and neck was almost normal and the patient looked much thinner about the face than on admission. A troublesome cough developed a few days after admission but quickly cleared up. Night-terrors, in which the patient seemed to be living through his accident again, were present from the start, but soon disappeared under the influence of bromides.

Several pathological investigations were carried out on this case, but no marked deviation from the normal blood CO₂, alveolar CO₂, and basal metabolism could be detected. A detailed qualitative and quantitative examination of the urine likewise revealed nothing abnormal.

Two Unpublished Cases.

About 40 cases of this condition have been described and two other unpublished cases were admitted to the Middlesex Hospital under the late Sir Alfred Pearce Gould in 1911; they are as follows:—

CASE 2.—A male, aged 20, was crushed between a lift and trap-door and held in this position for five minutes. He was admitted quite unconscious and bleeding from the nose. His extremities were cold and pale and his limbs flaccid; his face and neck down to a sharp line at the level of his thyroid were deeply cyanosed and almost black. There was marked dyspnoea and a frothy blood-stained fluid was expelled from the mouth with each breath. The eyes bulged; the pupils were slightly dilated and did not react to light; the corneal reflex was absent. Oxygen was administered for an hour and the colour improved. Fifteen minims of ether were administered subcutaneously. The tongue was now found to be much swollen, and on pulling it forward respiration was much improved. The patient became very restless and delirious, requiring restraint, but about four hours after the accident he had regained consciousness; the cyanosis was less, but the face was still very swollen. Subconjunctival hemorrhages appeared and the pupils now reacted to light. By next day patient was much improved; the pulse-rate had dropped from 160 on admission to 88, and the respirations were now only 20. A few signs appeared in the chest at the left base, but soon cleared up; the colour of the face and neck was normal by the fourteenth day.

CASE 3.—A very mild example of this condition. A female, aged 16, was run over by an omnibus, the wheel of which passed over her chest. Consciousness was not lost, but some disturbance of vision occurred. On admission the patient was slightly cyanosed about the head and neck, but there was no definite line of demarcation. (This is interesting in view of the absence of a collar in this case—see account of pathology below.) Respirations were rather hurried and subconjunctival hemorrhages appeared. The patient's condition was practically normal within a week.

Remarks.

The pathology of this condition is somewhat obscure, but from the literature of the subject several interesting facts emerge. Beech and Cobb² recorded a case in which a man was crushed in a freight elevator and presented the features of traumatic asphyxia. A portion of the discoloured skin was removed and microscopically the sole lesion found was a capillary dilatation, no blood being seen outside the vessels at all. Following the description by Beech and Cobb of their own and other cases, a mechanical theory for this dilatation was propounded, which is well summarised by Linington.³ He states that in the dissecting room it has been shown that the external jugular and to a less extent the internal jugular and vertebral veins are much less protected by valves than the subclavian veins. The pressure on the abdomen and thorax in accidents of the type described forces the venous blood into the right side of the heart, which, much engorged, allows a back pressure to take place into the superior venous system of which the superficial and less protected external jugular bears the brunt.

The "collar line" is produced by the counter pressure of the patient's collar preventing the venous dilatation; that this is so is borne out by a case (Bolt, quoted by Despard⁴) in which the patient was wearing a cap when the accident occurred and a non-coloured line was present where the cap had fitted the head. The cyanotic colour is thought to be due to the stagnation of de-oxygenated blood in the over-distended venous capillaries. Hueter, quoted by Beech and Cobb,⁵ produced this condition in rabbits by compression of the abdomen, and he concludes that part of the effect is due to pressure on the sympathetic nervous system of the abdomen and thorax, which helps to produce a vascular dilatation. In the case (1) described above it is interesting to note in this connexion that the right pupil was slightly dilated and that the right side of the trunk seems to have received the worse crushing.

From the clinical standpoint the condition can be diagnosed by the history of a crushing accident and the presence of a definite collar line. Treatment should be directed towards stimulating the respiratory centre and preventing the watery exudate into the bronchioles that frequently occurs in this condition; the administration of oxygen, combined with the use of heroin and atropine, seems to have given good results. The immediate prognosis should be guarded; the asphyxia may be progressive and terminate fatally, as in a case described by Russell.⁶ The ultimate prognosis is very good and a recognition of the terrifying condition will reassure anxious friends in a dramatic fashion.

I publish this case by kind permission of Mr. Shorney Webb.

DEATH OF DR. J. H. CAMPBELL.—James Hamilton Campbell, M.D., C.M. Glasg., who died on June 12th at his residence in Glasgow, graduated in medicine and surgery at the University of that city in 1890. After holding junior house appointments at the Glasgow Royal Infirmary, he took up the practice which his father had carried on at Partick. An enthusiastic cricketer, his name was so closely identified with the game that on his death being announced the mid-week matches of the West of Scotland Club were postponed. Dr. Campbell left a wife, a son, and three daughters.

A CASE OF LYMPHÆMIA.

By A. E. RUSSELL, M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL, LONDON;

LEONARD S. DUDGEON, C.M.G., C.B.E.,
F.R.C.P. LOND.,
DIRECTOR OF PATHOLOGY, ST. THOMAS'S HOSPITAL;

AND

A. L. URQUHART, M.B., CH.B. EDIN.,
ASSISTANT PATHOLOGIST AND BACTERIOLOGIST, ST. THOMAS'S
HOSPITAL.

THE patient was a male who at the date of his death in July, 1921, was 49 years old. He was a healthy active man until the onset of lymphæmia, and there was nothing of importance in his previous history. During the war he served in the Gallipoli campaign and subsequently went to the United States to carry out experiments with poison gas. Whilst in America he first noticed enlargement of the cervical glands and he was found to be suffering from lymphæmia; he was ordered small doses of arsenic which he took irregularly. He first came under our notice in January, 1919, and the clinical progress of the case with the alterations in the white cell content of the blood were observed over a period of two years and six months. Charts 1 and 2 have been prepared to show the successive changes in the white cell content of the blood. The lymphocytes (represented by an interrupted line) include both the large and small types of cell, and also the intermediate type, which was found to be the most common variety whilst the patient was under observation. The large hyaline cells, the eosinophil and mast cells are included in the total white cell figures, but as they were never present in the blood in abnormal relative proportions at any time during the illness they will not be referred to further.

Clinical Observations.

The period during which these observations were made may be divided into four parts for the purpose of description: (1) The condition when the patient first came under observation; (2) the acute exacerbation; (3) the period of quiescence; (4) the final illness.

1. *Condition at Period of First Observation.*—When the patient first came under our notice on Jan. 14th, 1919, his condition was as follows: Cervical glands of both sides so enlarged as to produce gross deformity; axillary glands moderately and inguinal glands slightly enlarged. Spleen easily felt on inspiration; its edge round and hard. Nothing further found on physical examination and patient felt fairly well. The blood count was as follows: Red cells 6,125,000 per c.mm.; leucocytes 18,000 per c.mm.; differential count: polymorphs 30 per cent., small lymphocytes 50 per cent., large lymphocytes 16 per cent., large hyalines 4 per cent. Both total leucocyte count and differential count were inaccurate, as many cells were degenerated beyond recognition and only showed as faint bodies.

Patient was at once put on liquor arsenicalis, three minims t.d.s., and this was gradually increased, but six minim doses were the largest he could ever tolerate without diarrhoea. The cervical glands rapidly diminished in size, and in three months had completely subsided; no subsequent re-enlargement of these glands occurred. Axillary glands also diminished in size, but never returned to normal. Blood count improved considerably; he continued taking arsenic until April 7th,

when he went to the Channel Islands for a five weeks' holiday. During this holiday the acute exacerbation commenced.

2. *Acute Exacerbation.*—On the patient's return from his holiday on May 15th, 1919, the leucocytes were found to number 78,000 per c.mm.; eight days later they had risen to 115,600 per c.mm., the highest count ever reached. This period of acute exacerbation lasted a little over three months and is represented graphically in Chart 1. The condition of the blood was observed on 12 occasions and it will be seen that the curve of the lymphocytes follows closely the curve of the total white cells throughout the acute attack. At the height of this attack, on May 23rd, the total white cells rose to 115,600 (110,000 lymphocytes, 3000 polymorphs). It will be noted that throughout this period the polymorphs were highest in the count of July 8th (6700) and lowest in that of July 21st (890), but the average count was not far removed from 4000 per c.mm. This may be taken as the average of a normal blood—i.e., a blood containing 6000

CHART 2.

Quiescent period following on period of exacerbation, and lasting from November, 1919, till the final illness of June, 1921.

white cells per c.mm. should contain 70 per cent. of polymorphs and 25 per cent. of lymphocytes, giving a total content of 4200 polymorphs and 1500 lymphocytes per c.mm. The lymphocyte content of the blood during this period was never less than 9000 per c.mm. and at the height of the attack reached 110,000 per c.mm.

He was admitted into St. Thomas's Hospital for three weeks; arsenic administered throughout this acute phase. Benzol also given, commencing with 5 minims, then 10 minims, and finally 15 minims, twice daily. Benzol discontinued on June 18th after 34 days' administration; by July 8th leucocyte count had dropped to 29,300 per c.mm., but rose again to 43,400 by August 5th. On the 9th benzol was resumed for a further period of 18 days, when it was again discontinued, the leucocyte count having dropped to 10,480. Reaction of blood to benzol is well shown on Chart 1.

During this period the number of red cells was also estimated; this acute phase had no material influence on the red cell count.

1919.		Hæmoglobin per cent.	Colour index.
June 8th	5,400,000	82	0.75
„ 16th	5,200,000	80	0.77
„ 24th	5,070,000	80	0.80
July 8th	4,960,000	83	0.83
„ 21st	4,730,000	80	0.84
Aug. 5th	5,520,000	94	0.85

3. *Period of Quiescence.*—The acute stage lasted for three months, after which the blood picture settled down to a fairly constant level from November, 1919, until the final illness of June, 1921. During this time he was in fairly good health, able to do his work efficiently and without fatigue. Arsenic was given with occasional remissions of a few weeks, and he slowly developed a moderate degree of bronzing of the skin. Axillary glands remained slightly enlarged, but spleen diminished, and at times could not be felt. During this period (Chart 2) total number of white cells varied from 6000 to 10,000 per c.mm. On three occasions, in early part of period—Nov. 4th, 1919, Jan. 7th, and Feb. 3rd, 1920—normal counts were recorded both in total number of cells and in proportion of lymphocytes and polymorphs. For rest of period, proportion of polymorphs and lymphocytes almost equal, but towards the end lymphatic cells had again shown a very pronounced rise, although total number of cells remained about 10,000 per c.mm. Red blood cells during this period remained at about 5,000,000 per c.mm.

4. *Final Illness.*—On June 15th, 1921, he was taken ill with cough and fever; admitted into St. Thomas's Hospital on June 17th. Coarse friction present in left axilla; on June 22nd slight tubular breathing developed at apex of

CHART 1.

Period of acute exacerbation of lymphæmia, lasting over three months.

left lung. Soft râles audible throughout whole of this lung, and by July 1st left upper lobe showed the usual signs of consolidation, which persisted till the end. A moderate amount of sputum brought up, occasionally very slightly rusty. Tongue coated with brown fur in the earlier days, but later glazed and dry. Herpes not present. No purpuric eruption occurred and careful daily examination failed to discover a single petechial spot. Pulse-rate at first ranged between 90 and 100, and gradually increased in rapidity to about 140, presenting nothing unusual. The blood pressure varied between 100 and 130. Mental condition singularly clear throughout, though towards the end slight wandering and confusion developed. Intestinal hæmorrhage occurred on June 27th, 28th, and 30th; bulky stools of ordinary melæna type being passed. A few rose spots were noted on the abdomen on July 8th, death occurring on the following day.

In addition to general stimulants such as camphor, digitalin, and adrenalin he received three injections of an autogenous pneumococcal vaccine, and two intravenous injections of 1/32 gr. perchloride of mercury. These latter were each followed by a rigor and temporary collapse of such severity as to negative further injections. Four doses of benzol (M xv.) were given between June 27th and 29th, but we did not think it justifiable to give more.

Pathological Findings.

A blood culture was made on June 21st and some 5 c.cm. of blood were taken into tubes containing 20 c.cm. of glucose broth and distilled water. After 12 hours' incubation a heavy growth of diplococci was present in broth cultures. This organism proved to be a pneumococcus which agglutinated with type 1 antipneumococcal serum. The pyrexia continued and blood cultures were repeated on June 27th and 30th, and July 5th, and on all occasions the pneumococcus was isolated. In the culture made on the 5th, after melæna had been present for some days, a streptococcus was present in the blood culture and also a Gram-negative bacillus which gave the "sugar" reactions of the paratyphoid C bacillus (1920 and 1921), and when first isolated agglutinated to 50/6000 with paratyphoid B antiserum and 2000/5000 with paratyphoid C antiserum, made from a "C" strain obtained by us in the Balkans. Later, after several subcultures, the bacillus agglutinated to 500/6000 with paratyphoid B. and 5000/5000 with the paratyphoid C antiserum.

The blood serum was tested on three occasions, June 27th and 30th, and July 5th for type 1 pneumococcal agglutinins, but was negative throughout; on the last occasion the serum was also tested for agglutinins to typhoid and paratyphoid A, B, and C, but no reaction with a 1/25 dilution was observed. The stools were examined during the period of melæna for the presence of pneumococci, the faeces being plated on MacConkey and blood agar (Wordley, 1921). No pneumococci were isolated, nor was the presence of non-lactose-fermenting colonies noted on the MacConkey plates.

The blood condition during the final illness (Chart 2) is of interest. A leucocytosis which reached 38,000 per c.mm. developed. The polymorphs on June 17th numbered 10,000 per c.mm., two days after the onset of the illness; by the 30th they had dropped to 5900 per c.mm., but rose again to 10,200 on the last occasion on which the blood was examined. The lymphocytes, which numbered 9000 per c.mm. on the 17th, rose to 31,900 per c.mm. by the 30th, and showed a slight fall to 27,300 in the count of July 2nd. The terminal leucocytosis, after a period of 14 days of pneumococcal septicæmia, was entirely lymphocytic in character. The red cell content of the blood during the final illness showed a loss of almost 50 per cent., as the following figures show:—

Date.	Red cells.	Hæmoglobin per cent.	Colour index.
June 27th ..	4,270,000	80	0.92
" 30th ..	3,460,000	60	0.88
July 2nd ..	2,600,000	52	1.0

During this period melæna was present, but this serious loss of red cells could scarcely have been due to this cause alone.

Pathologically this case presents several features of interest. The acute leukæmic condition in which the white cells rose to 115,000 per c.mm. was due to an increase of the lymphocytic cells of the blood, the number of polymorphs remaining practically normal throughout the attack. During the quiescent period normal blood counts were obtained, but usually the proportion of lymphatic cells was increased. In the period of final illness, although a pneumococcal septicæmia persisted for at least 14 days, the leucocytosis, which was present, was due to a lymphatic increase in the white cells; no polymorph reaction was observed. The presence of three separate types of organism is an uncommon feature even although the culture was taken towards the end of a fatal illness, complicated by the presence of melæna. The paratyphoid C infection may have been derived from a convalescent case of this disease in a ward adjoining that into which our case was admitted.

RADIUM IN THE TREATMENT OF UTERINE HÆMORRHAGE,

WITH A REPORT UPON FORTY-FIVE CASES.¹

BY SIDNEY FORSDIKE, M.D., B.S. LOND.,
F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS, HOSPITAL FOR WOMEN, SOHO-SQUARE;
GYNECOLOGICAL SURGEON TO THE KENSINGTON AND
FULHAM GENERAL HOSPITAL.

SEVERE and persistent uterine hæmorrhage, at any age, is a source of infinite anxiety to both the patient and doctor, and when the latter has exhausted the long and too often futile list of drugs, together with prolonged periods of rest in bed, he is constrained to recommend curettage. Many of the less severe cases are relieved by this measure; but in the type of case under consideration, relief, if any there be, is only measured in weeks. The patient is too soon in the status quo ante, and it becomes clear that something more radical must be undertaken. At or near the menopause the above palliative measures may suffice to pilot a patient through a stormy climacteric into the back-waters of post-menstrual life—only too often, however, at the cost of transforming her into a semi-invalid with the late prospect of complete neurasthenia. While this method is possible for the well-to-do patient who can afford to remain in bed, it is not feasible for the wage-earner or the mother of a family, and other means must be adopted to deal with the condition promptly and finally.

The methods advocated for this condition are: (1) Hysterectomy; (2) X rays; (3) radium; and the analysis of a report upon 45 cases treated by radium tends to show that it is the treatment of choice when available.

Selection of Cases.

The type of case under consideration is sometimes described as the "bleeding uterus"—a most descriptive term; more commonly it is labelled chronic metritis, fibrosis uteri, or chronic subinvolution. However debatable the pathology, the one distinctive clinical feature is excessive and uncontrollable hæmorrhage with absence of any pelvic lesion to account for it. This series of cases does not include those with ordinary causes of hæmorrhage; it includes only cases which had been dealt with in the usual way and had proved refractory to treatment. The criteria by which cases were selected were: (a) The persistence of severe hæmorrhage after operative treatment; (b) an advanced anæmia, with shortness of breath, headaches, cedema of legs, &c., which had been treated palliatively for some time; (c) cases where the patient had to spend some part of each month in bed.

¹ A paper read before the Section of Obstetrics and Gynecology of the Royal Society of Medicine on March 1st, 1923.

Excluding three cases in which an effort was made to modify the period rather than to stop it, there were 42 cases, the youngest being 29 years and the oldest 55 years. Three only were unmarried, and of the 39 married four only were nullipara.

Details of Series.

Number and Types of Operations.—Of the 45 cases 26 had undergone some form of operation or combination of operations, including dilatation and curettage, removal of polypi, amputation of cervix, oöphorectomy or salpingo-oöphorectomy, and some of the cases had been curetted more than once. The remaining cases had undergone medical treatment for variable periods or were so anæmic as to forbid any further effort at palliation.

Clinical Types.—Four cases were associated with fibroids, two of the interstitial variety, and two with small subperitoneal fibroids. The results were equally satisfactory, and no change could subsequently be detected in the subperitoneal tumours. While all the uteri were enlarged, they were broadly divisible into two groups which might be best described as (a) systolic uterus and (b) diastolic uterus. The systolic uterus was hard, firm, and regular, commonly straight and admitted a sound for from 3 to 3½ inches; it yielded little or no tissue to the curette and gave the characteristic rasp of fibrosis uteri. The diastolic uterus was bulky, retroverted, admitted a sound from 3½ to 5 inches, and generally yielded a thickened and oedematous tissue. An interesting point about this type of uterus was the fact that some months after irradiation it was indistinguishable from the systolic type.

Technique.—In all cases dilatation of the cervix and exploratory curettage were performed. Where the cervix and vagina were septic a preliminary cleansing treatment was carried out. In all cases the radium was placed in the uterine cavity, and only the gamma ray was utilised. The vagina was packed with gauze moistened with liquid paraffin, with the two-fold object of supporting the radium and of keeping the bladder and rectum away from the source of energy. A further precaution was adopted to maintain the bladder in a flaccid condition by the introduction of a self-retaining catheter into the viscus. In some cases it was necessary to stitch the vulva in order to support the vaginal plug.

Dosage.—In three cases of patients between the ages of 20 and 26, 50 mg. of radium were used for five hours. In the other cases 100 mg. were used for 24 hours, the object in the former cases being to influence the menstrual period, in the latter cases finally to end it. I am inclined to think that 100 mg. is an unnecessarily large quantity for the purpose, for in some later cases 75 mg. appear to have had the desired effect. A certain number of cases complained of pain while the radium was in utero, but no more than when a stem is left in the cervix, and it disappeared promptly with the removal of the radium. In a few cases post-anæsthetic vomiting was prolonged; it was quickly relieved on withdrawal of the radium. Some patients noted a frequency of micturition following irradiation, a condition which was quickly relieved by barley-water, citrate of potash, &c. Beyond the above, no untoward symptoms were noted. In all cases nocturnal douches of salt and water are suggested for a period of six weeks following the radiation.

Classification of Cases.—The cases were classified as follows:—

Group.	Age.	Cases.	Group.	Age.	Cases.
A	= 20-26	3	C	= 39-50	22
B	= 29-38	10	D	= 51-55	10

Details of Cases.

Group A will be considered in detail; the condition found and result of treatment in the other groups will then be summarised.

CASE 1.—Aged 20, married, no children. For one and a half years had been losing 14-21 days at a time and was only clear from 7-10 days. Dilatation and curettage in September,

1921, did not relieve her at all; she attended hospital as an out-patient in October, November, and December, and it was clear that something more would have to be done. In January, 1922, 50 mg. radium were introduced into the uterine cavity and left there for five hours. Late in January she had a period of four days, and from Feb. 28th another period lasting four days. In March and April more severe periods. In May she was admitted to another hospital, where an ovary was removed. Since then she has been quite well.

CASE 2.—Aged 23, a Jewess, single. Had been losing daily for seven months and was very anæmic; had already been in hospital twice for the same condition, the first time for six weeks' observation and palliative treatment, the second time for dilatation and curettage, after which she was better for three months, but then relapsed into the daily loss. She was now thoroughly demoralised, and despite her religion was anxious that hysterectomy should be done. In February, 1921, I dilated the cervix and introduced 50 mg. of radium sulphate into the uterus, leaving it there for five hours. She bled steadily for 11 days, during which time the vagina had to be plugged. For the next six months she was regular for from four to six days, during which time she was in sole charge of a hemiplegic father, and since then she has had no period at all. This, I think, must be attributed to the close confinement and hard work involved rather than to the influence of radium.

CASE 3.—Aged 26, married, no children. Had severe periods with pain for four years since marriage, necessitating a couple of days in bed per month. She was anæmic and had been treated with drugs for a considerable time. In January, 1921, 50 mg. radium sulphate was placed in utero for five hours. She has been regular every month since, three-day type without symptoms.

Group B.—Ages 29-38. There were ten cases; eight had had some form of operation, and two had been treated palliatively and had become steadily worse.

Group C.—Ages 39-50. Twenty-two cases; 11 had had some form of operation, and 11 had been treated palliatively, but with advancing anæmia and persistent hæmorrhage.

Group D.—Ages 51-55. Ten cases; five had had some form of operation and five had been treated palliatively.

Symptoms Following the Radium.

There was no further loss in ten cases; one period in 17, two periods in 11, and three periods in 4. The periods usually consisted of long-drawn-out "shows" varying from three days to three to four weeks, the actual quantity of blood lost being small. Exposure given immediately before a period usually resulted in a severe loss. In five cases radium had to be employed a second time; in three the first exposure would probably have sufficed, but the patients were so thoroughly frightened by two prolonged shows following the first exposure that it was deemed advisable to comply with their demands. In only two of these five was an anæsthetic necessary.

Vaso-motor Symptoms.—Flushing as an index of vaso-motor disturbance is liable to a very considerable margin of error, and consequently is open to legitimate criticism. Many women will omit mention of this symptom in a carefully-taken history, yet, when it is suggested to them, they will admit experiencing the symptom occasionally; where flushing is a real signal symptom it is mentioned spontaneously. The graver vaso-motor changes, as signified by a profuse perspiration or a generalised fall in blood pressure, are never omitted in the history, for they produce considerable distress. Consequently I listen patiently to the history, and if they do not mention vaso-motor symptoms I have carefully refrained from asking them, and in the after-result it was a fair conclusion that such symptoms did not exist.

In group A there were naturally no symptoms. In group B eight patients had no symptoms, and two complained of flushes; in this group vaso-motor symptoms might have been expected on the assumption that the ovary was being affected. In group C nine patients had no symptoms, four had flushing, three had flushing and sweating, and six complained of flushing before treatment which remained the same afterwards. In group D six suffered from flushes

before treatment and remained much the same; four made no mention before or after.

Causation of the Radium Menopause.

Is the radium menopause due to action upon the uterus, or upon the ovary, or upon both? The available evidence points to action upon the uterus solely in the majority of cases, and is based upon (a) clinical, and (b) experimental grounds.

Clinical Evidence.

In the younger women, aged from 29 to 38, only two out of ten mentioned flushes, where this symptom should have been pronounced, on the assumption that the ovary was influenced. Again, in the group aged 39-50 the symptom was not unduly increased, and only in three cases was sweating added to flushing. Histological evidence is difficult to obtain, for removal of the uterus following treatment by radium for this condition must be very rare. However, by the courtesy of Dr. Miles Phillips, of Sheffield, I have examined sections from two uteri after exposure to radium, and a section of the ovary from one of the cases; in the uterine sections there was a diminution in the number and size of the glands of the endometrium, and fewer capillaries than normal, but in the ovary there was no change suggestive of irradiation.

Experimental Evidence.

The normally placed ovary is 8 cm. away from the uterine cavity, and beyond the effective range of radium, but a prolapsed ovary would be very much nearer, and to some extent would account for variable results. The uterus of a cat being bicornuate, the conditions under which radium is used clinically can be reproduced by the implantation of the radium in one horn whilst the contra-lateral ovary is fixed by a stitch at 8 cm. distance from it. The experiment was performed in this way. A pregnant horn was opened and the foetus removed; the radium was then implanted and the horn closed by suture. The ovary of the same side was lightly attached to the wall of the uterus, and the opposite ovary was fixed at a distance of 8 cm. by suture and rubber tube. The radium was removed in 24 hours' time. This experiment was repeated, the animals being killed at intervals (12, 21, and 60 days).

In none of the experiments did the contra-lateral ovary show any macroscopic or microscopic change. In all the experiments the ovary, of the irradiated side, shows a profound change which varies and becomes increasingly severe with the prolongation of life subsequent to the exposure to radium. There is destruction of all the follicles, an increase of connective tissue, diminution of capillaries, and finally the ovarian tissue cannot be identified.

Changes in the Uterus.—The endometrium is notably attenuated to the extent of one-quarter or even one-sixth of the normal depth, and the stroma cells are largely replaced by connective tissue. The capillaries are fewer, and the uterine glands are much fewer in the shorter survivals after exposure; they have entirely disappeared in the experiments where the animal lived for two months after irradiation.

Contra-indications.—The only contra-indication is a previous pelvic inflammation; this is a very real danger, for the pelvis may become filled with an inflammatory tumour rising into the abdomen, the nucleus of which is an abscess seated deeply in the pelvis and which is very difficult to deal with. A case of this kind has occurred to me in treating a carcinoma of the cervix, where the risk had to be taken in order to treat the growth.

Relative Advantages of Radium, X Rays, and Operation.

Radium.—Radium is suitable for all cases except those complicated by inflammatory disease. There is no mortality and no morbidity, and the minimum amount of time is necessary for treatment—from three to seven days. There is no prolonged convalescence or stay in hospital or nursing-home. There were no failures in this series. The one drawback is the comparative scarcity of radium.

X Rays.—The use of X rays for the treatment of severe uterine hæmorrhage has been fairly successful, but is accompanied by very definite drawbacks. First, the X rays are utilised to destroy the ovaries; their use raises the objection that normal organs are being destroyed in order to influence an abnormal organ, and this is accompanied by a considerable proportion of cases exhibiting severe vaso-motor symptoms (38 per cent., according to Eden and Provis). Secondly, the treatment is prolonged, lasting three to four hours on two succeeding days, repeated at intervals of 21 days on four to six occasions. Thirdly, there is a danger that the treatment may be used without a diagnostic curettage. Fourthly, ulceration of the bowel, superficial burns, &c., have been noted. Finally, a certain number of failures have been noted.

Hysterectomy.—Despite its low mortality, hysterectomy is a severe operation, frequently associated with post-operative results which are difficult to assess—e.g., the profound depression and loss of morale not infrequently seen. There is a more or less prolonged period of invalidism following any abdominal operation, and a certain percentage of morbidity as shown by subsequent pain, herniæ, adhesions, and constipation. Nevertheless, the operation is satisfactory inasmuch as the bleeding is cured; the only criticism is that the subtotal operation leaves a useless cervix, too often a diseased cervix, and less frequently a cervix which may become the seat of a malignant growth, of which I have met one example this year. The drawbacks of this treatment to the wage-earner are the necessary length of stay in hospital and convalescence, and the problematical complete restoration of health.

Conclusions.

1. In my opinion radium treatment should be the method of choice in all uncomplicated cases of severe and persistent hæmorrhage due to chronic metritis, inflammatory disease of the tubes and ovaries constituting the sole contra-indication.

2. The radium menopause is not usually accompanied by any symptoms attributable to action upon the ovaries, and of all methods it produces the least disturbance of the patient's economic life.

Clinical and Laboratory Notes.

A NOTE ON THE DETECTION OF COAGULABLE PROTEIN IN FÆCES.

BY ROBERT COOPE, M.D., B.Sc. LIVERP.,
M.R.C.P. LOND.,

LECTURER IN BIOCHEMISTRY, UNIVERSITY OF LIVERPOOL;
HONORARY ASSISTANT CHEMICAL PATHOLOGIST,
LIVERPOOL ROYAL INFIRMARY.

(From the Department of Biochemistry, University
of Liverpool.)

THE difficulty of obtaining a clear filtrate from an emulsion of fæces, and the slowness with which an adequate amount of filtrate is obtained by the usual procedure, are probably responsible for the fact that comparatively few observations have been made on the presence of coagulable protein in stools. The significance of fæcal albumin has already been discussed in an earlier communication.¹ For the past two years I have investigated the clinical utility of an improvement in technique devised by Prof. W. Ramsden (here published at his request), whereby perfectly clear fæcal filtrates, suitable for protein-precipitation and coagulation tests, are obtained with comparative ease and rapidity.

The improvement consists in "half saturating" the fæcal emulsion with ammonium sulphate before filtration. It was based on the expectation that in this environment the voluminous soap gels would

¹ R. Coope: THE LANCET, 1920, II., 291.

encapsule all fat globules and bacteria, and at the same time shrink up into floccules readily removable by filtration. The test has the disadvantage that it detects only albumin, as any globulins originally present are salted out with the soaps. There is no evidence, however, that globulins, unattended by albumins, ever occur in fæces, and the above disadvantage is more than compensated for by the clearness of the filtrate, and the corresponding increase in delicacy of the albumin tests. Further, with the old procedure it was many hours or even days before enough clear filtrate was obtained for the test, whereas with the present method half an hour usually suffices.

About 20 g. of fæces are taken, and worked up with twice the weight of water—i.e., about 40 c.cm. at 50° C.—to a homogeneous cream. An equal volume of a saturated (54 per cent.) solution of ammonium sulphate is added and well mixed, and the mixture is filtered through ordinary filter paper. If the first runnings are turbid—as is sometimes the case, especially in the light yellow stools of a milk diet—they should be returned until the filtrate comes through perfectly clear. If the original fæces are fluid, the ammonium sulphate solution is added without previous dilution with water.

Five to ten c.cm. of the clear filtrate are taken, and tested for albumin by heat coagulation. Salicylsulphonic acid may be used as a confirmatory test. Trichloroacetic acid is not allowable, as it often produces some turbidity even in the absence of coagulable protein.

The reaction is positive only when a definite turbidity develops; on standing for some time a flocculent coagulum sinks down to the bottom of the test-tube. Occasionally very slight turbidities, only recognised with difficulty or when the test-tube is put into reflected light, occur in apparently normal stools. They should be disregarded. On boiling the filtrate there is often a perceptible change in colour, which must not, of course, be mistaken for the development of a slight turbidity.

The reaction of the fæcal filtrate is usually slightly acid, and it has never been found either too alkaline or too acid for heat coagulation. It should be added, however, that artificial acidification of the fæcal emulsion, even by so feeble an acid as boric acid, makes filtration very slow (owing presumably to clogging of the filter by free fatty acids), and the filtrate tends to be turbid.

The delicacy of the test varies considerably with different stools. In a series of control experiments, the minimal amounts of added blood serum which were detected in 100 g. of original fæces ranged from 0.125 to 0.5 c.cm. In infants a positive reaction is frequent, especially in diarrhoeic stools. In older children and adults, however, the presence of fæcal albumin is almost invariably due to some pathological process—usually bleeding, or exudation of serum into the gut. In a series of over 250 non-infantile stools, I have had but two positive findings to which no pathological explanation could be definitely assigned. The first was that of a laboratory worker, who during a severe cold showed fæcal albumin for two days. The other was that of an old man with obscure gastric symptoms, who was inordinately fond of black puddings. In both cases the albumin disappeared with the adoption of a milk diet.

NOTES ON TWO CASES OF ERYTHRÆMIA TREATED BY X RAYS. BY E. J. STOLKIND, M.D. MOSCOW AND SIENA.

THE following two cases¹ of erythræmia, or splenomegalic polycythæmia, successfully treated by X rays, are of interest.

CASE 1.—A male, aged 50, complained of frequent attacks of giddiness, weakness, fatigue, pain, &c. He had always enjoyed good health. About five and a half years ago he was suffering from loss of considerable quantities of blood (from hæmorrhoids), during which time he became so weak that he could not move. In February, 1921, he had hæmoptysis. At the end of 1921 he came to the West End Hospital for Nervous Diseases.

¹ These cases were shown in the Clinical Section of the Royal Society of Medicine on Feb. 9th, 1923.

Condition on Examination.—Severe cyanosis of the face, ears, lips, tongue, mouth, fauces, with bluish-red hands, cyanotic clubbed fingers, and injected conjunctivæ. Many cutaneous telangiectases on the face. Spleen felt about two fingers-breadth below costal margin, and tender. Liver also enlarged and palpable. Ophthalmoscopic examination revealed abnormally large veins in each fundus (fundus polycythæmicus). Urine contained albumin. Patient denied syphilitic infection, and Wassermann reaction was negative. Brachial blood pressure (Riva Rocci) 140 (systolic) and 90 (diastolic). The patient complained of intermittent pain in the right mandibular joint and of pain on movement of the joint, and of occasional cramps in the limbs, numbness in the legs, &c. He was unable to follow his occupation.

Blood Examination.—Blood counts on March 31st, 1922: Erythrocytes, 9,500,000; hæmoglobin, 150 per cent.; colour-index, 0.8; white cells, 16,400; polymorphonuclear neutrophils, 71 per cent.; eosinophiles, 2 per cent.; large mononuclears, 10 per cent.; small mononuclears, 14 per cent.; transitionals, 2 per cent.

Treatment.—For more than seven weeks I tried benzol from 3 to 6 c.cm. per diem, but it reduced the number neither of red cells and hæmoglobin, nor of white cells, and did not improve the subjective condition of the patient. For six months he was treated by sodium iodide, also without much subjective improvement. Blood count: Red cells, 7,700,000; hæmoglobin, 140 per cent.; white cells, 21,000. Venesection was tried without success.

From Nov. 16th to Dec. 29th, 1922, Dr. J. H. Douglas Webster made 11 full applications of intensive Röntgen rays (38 cm. alternate gap) to sternum, thighs, legs, and arms. The blood count two weeks after the last application was: Red cells, 7,000,000; hæmoglobin, 140 per cent.; white cells, 12,000; polymorphonuclears, 79 per cent.; eosinophiles, 1 per cent.; monomorphonuclears, large 6, small 13 per cent.; transitionals, 1 per cent.

Röntgenotherapy of the bones was of considerable use; it relieved the pains in the limbs, &c., and generally improved the subjective condition of the patient. He is now much stronger; the limbs are not so heavy, and he feels no more painful cramps; he can now easily move his head in all directions, and walk freely; he is not so shaky.

CASE 2.—A woman, aged 43, had been suffering at times from bleeding from the nose and gums, headaches, rush of blood to the head, red face, tinnitus aurium, &c. Brachial blood pressure: 200 (systolic) and 140 (diastolic), Riva Rocci. Spleen palpable and enlarged. Blood count: Red cells, 7,600,000 to 8,300,000; white cells, 15,000; hæmoglobin, 105 to 115. This was also a case of erythræmia, and 14 X ray applications were made to the bones, resulting in considerable subjective improvement. Blood count ten weeks after the fourteenth application: Red cells, 5,600,000; hæmoglobin, 123; white cells, 11,200; four and a half months later when examining the patient, I found: Red cells, 8,500,000; white cells, 10,900; hæmoglobin, 115; but the patient no longer complained of any symptoms.

I have to thank Dr. Braxton Hicks for the blood examination in Case 1, and Dr. H. Guggenheimer for the opportunity of examining Case 2.

Hampstead, N.W.

SURVIVAL OF SPLENIC TISSUE AFTER SPLENECTOMY.

BY RICHARD T. LEE, M.B., CH.B. SHEFF., M.R.C.S.,
HONORARY SURGEON, MONTAGU HOSPITAL, MEXBOROUGH.

THE following case seems to be sufficiently unusual to be recorded.

Male, aged 29, admitted to the Montagu Hospital, Mexborough, on March 26th, 1923, suffering from abdominal pain, slight vomiting, and constipation.

History.—At the age of 14 he was climbing a wall which fell over on to him, crushing his abdomen. He was admitted to hospital and laparotomy was performed. The spleen was found to be ruptured and was removed. He enjoyed good health subsequently, up to the day previous to examination. He then had sudden abdominal pain and vomiting, and was unable to get his bowels moved. He was able to pass flatus.

Condition on Examination.—Temperature normal, pulse 80 per minute. Tongue coated. Abdomen moved with respiration. Laparotomy scar in middle line above umbilicus. Slight tenderness all over abdomen. Nothing abnormal on palpation or percussion. The vomited matter was bile-stained mucus. An enema was given, which relieved the vomiting and most of the pain. This was repeated on the

morning of the 27th. That evening the pain and vomiting returned; examination of the abdomen showed maximum pain and tenderness over McBurney's point. On the morning of the 28th the pain was worse and the vomiting continued.

Operation.—At 11.30 A.M. on the 28th the abdomen was opened through right rectus below umbilicus. Distended coils of small intestine bulged into the wound. These were studded with small sessile, greenish-black tumours. Exploration revealed a band extending from the old scar to small intestine and a coil of small intestine twisted over it. The band was divided, and the strangulated intestine, being in good condition, was returned to the abdomen. The appendix was normal; the splenic region was not explored. The whole of the peritoneum covering the small intestine and mesentery was found to be covered with small tumours, varying in size from that of a pin's head to about one inch by half an inch. They were either sessile or pedunculated, and appeared only to involve the peritoneal covering of the gut. There were perhaps 200 to 300 tumours. The general appearance suggested splenic tissue;

they appeared to be quite innocent in character. Two were removed for examination and the abdomen closed. Recovery was uneventful.

Microscopical Examination.—One specimen was sent to the Pathology Department, University of Sheffield, for microscopical examination. The following is the report: "This is a small mass of splenic tissue, containing pulp with sinuses and Malpighian bodies. The whole structure is covered by a dense fibrous tissue capsule, and the trabeculae show increased amount of fibrous tissue."

On inquiry from one of the medical men who was present at the first operation, I found that he had no recollection of anything abnormal other than the ruptured viscus. In this case, evidently, living splenic cells had been set free in the peritoneal cavity when the spleen was ruptured, and had become implanted on the peritoneum. The amount of splenic tissue so formed appeared to be quite equal to that in a normal spleen, so that the patient was provided with the equivalent of a new spleen.

Medical Societies.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

METASTATIC GONORRHOEA.

At a general meeting of this Society, held at 11, Chandos-street, W., on May 25th, Dr. DAVID WATSON, the President, in the chair, Sir THOMAS HORDER introduced a discussion on Metastatic Gonorrhoea by reading a paper which appears in full on p. 1304.

Sir WILLIAM WILLCOX said that gonococcal arthritis was of particular interest because it seemed to throw so much light on that much disputed condition known variously as rheumatoid arthritis, osteitis deformans, villous arthritis, &c. In a discussion on gonococcal arthritis should be included the various forms of fibrositis—namely, panniculitis, inflammation of fasciae, muscular rheumatism, inflammation of tendons and bursae, and many forms of perineuritis. These formed a very common complication of gonorrhoea. Some years ago a hunt servant developed gonorrhoea, and saw his local doctor. He had a brachial neuritis and some symptoms of general fibrositis, and was sent to Harrogate. Ultimately the speaker went to see this patient, and found that all the signs of malignant endocarditis, brachial neuritis, and urethritis were present, the urethritis having been contracted six weeks before the onset of the cardiac symptoms. The patient had not wished to give up his work, and so had continued to ride and hunt, the worst thing he could have done, as this massage to the prostatic region gave him a severe auto-inoculation, which proved fatal. Here the rheumatic symptoms were evidently only part of the picture, and not the primary one. As to the bacteriology, joints and tendons frequently failed to reveal the organism, but that did not exclude the possibility of the infection being gonorrhoeal. In gonococcal arthritis, however, the organism had been found in a relatively large proportion of the cases, compared with the other forms of arthritis. Koenig 15 years ago reported that in one-third of his cases of gonorrhoeal arthritis he was able to cultivate that organism. Barr obtained the organism in 19 out of 27 cases, and in 121 cases he found the organism 92 times microscopically and 21 times in culture. In gonococcal arthritis organisms were not necessarily in the joints. Wassermann did some experiments on himself, injecting into himself gonococcal toxins, in which the organism had been destroyed by heat; and he was able to produce symptoms of gonorrhoeal rheumatism.

The question of secondary infections was an interesting one. In many cases of gonorrhoea there was chronic prostatitis and stricture, and a streptococcal infection followed the gonococcal. In some

cases it seemed that the arthritis was due to the secondary infection rather than to the gonococcus, and that the latter might have died out. Latent gonococcal infections might last for years. Sir William Willcox quoted the case of a married man, aged 50, who had a bad gonococcal arthritis of the knee, and admitted indiscretions when about 21 years of age, but in whom there was no history of there having been venereal disease for 25 years. He had keratoderma blenorrhagica and on the soles of his feet were raised-up crusts of horny material, which gave pain on walking. The likelihood of arthritis being due to secondary infection applied specially to women; in them gonorrhoea might be followed by endometritis, salpingitis, and then secondary infection. Two years ago he saw a case in which there was a history of gonorrhoea having been acquired many years before; there had been no symptoms for seven or eight years, but there had been some ovarian trouble, and arthritis, following injury, developed in the left shoulder, and 12 months afterwards in the right ankle, and the right knee. It looked like an ordinary rheumatoid arthritis, but no definite focal infection could be found. A vaccine made from the streptococcus found in the stools gave no benefit. Then pelvic trouble developed, and there was typical salpingitis, for which the tubes were removed. These were examined, but only streptococci were found in them.

Ætiology.—With regard to ætiology, gonococcal arthritis might occur at any stage of the gonorrhoea, and many years might intervene between it and the original infection. Infants might very occasionally get arthritis from gonococcal ophthalmia, but cold, injury, strain, over-exertion might play a part in this as in other forms of arthritis. Gonococcal arthritis was said to be of more frequent occurrence in the male sex. The relationship of true acute rheumatism and rheumatoid arthritis to gonococcal rheumatism was of interest. Sometimes one saw patients who had had acute rheumatism and then got infected with gonorrhoea; in such an event the speaker's experience was that the gonorrhoeal infection was much more severe in its manifestations than usual. The same applied to arthritis. He had lately seen a patient with rheumatoid arthritis which was obviously due to dental infection; there were several apical dental abscesses. Treatment brought about a remarkable recovery. The patient went away for a few months, and when he returned he had a very bad arthritis. Questioning showed he had developed gonorrhoea in the meantime. The worst case of arthritis Sir William Willcox had ever seen was in a patient who had had acute rheumatism in childhood and in early adult life incurred a gonococcal infection; both his hips were completely ankylosed. If certain people had an infection, one particular system of the body might be preferentially involved, and rheumatic subjects acquiring gonorrhoea had a bad time. Gonococcal arthritis was not so common as acute rheumatism in this country, but in some States of America the reverse appeared from statistics to be true.

Pathological Anatomy.—With regard to the pathological anatomy of the condition, four different forms had been described: the hydrops articuli form, the sero-fibrinous, the phlegmonous, and the purulent type, in which pus occurred in the joint. There was a rarefaction of bone with formation of osteophytes; there was also much wasting of muscles, which some said was not merely due to the wasting consequent on the affected joints, but there might be in some cases actual gonococcal myositis. The periosteum might be involved, and a bony thickening of the shaft might be found.

Clinical Course.—As to the clinical course, the general symptoms might be very severe; there might be high pyrexia for weeks or months, also marked anaemia. Pain was a prominent symptom of the acute stage. A feature somewhat distinguishing gonococcal from ordinary acute rheumatism was that sweating was not such a marked accompaniment, and the condition did not flit from joint to joint to the same extent. Neither did it respond to salicylates as did acute rheumatism.

Involvement of Joints.—It had been said that gonorrhoeal arthritis was generally monarticular; the speaker believed that this was wrong, though one joint might be more severely involved than others. In a series of cases at the Johns Hopkins Hospital the average number of joints involved in gonorrhoeal arthritis was six, though perhaps in that series pain in a joint was accounted an indication of involvement; in cases of acute rheumatism the average number of joints affected was three. In order of frequency the following joints were affected in gonorrhoeal arthritis: knee, ankle, wrist, shoulder, elbow, hip, small joints of feet, small joints of hand, temporo-maxillary joint, sterno-clavicular, vertebral, chondro-costal. Spondylitis deformans was often due to a gonorrhoeal infection. Some said that this and painful heels were *always* due to the infection, but Sir William Willcox regarded this statement as incorrect.

In a case of gonococcal arthritis one would look for associated symptoms of gonorrhoea apart from the primary focus: for conjunctivitis, iritis, keratitis, and for skin conditions, such as keratoderma blenorrhagica or warts. In a series of arthritis cases described by Dr. George Graham, due to bacillary dysentery, conjunctivitis occurred in some 70 per cent.; therefore, an association of arthritis and conjunctivitis might mean dysentery. Sir Thomas Horder had already dealt with the subject of clinical diagnosis. Dr. A. Fleming, of St. Mary's Hospital, gave almost identical answers to those of Sir Thomas Horder's colleague in regard to the agglutination test; in Dr. Fleming's opinion the complement-fixation was not a very reliable test either.

Treatment.—Obviously the first thing to do was to attack the cause. The most important indication was rest. He believed many of the severe cases seen would not have reached that stage if complete rest had been insisted on for the patients early in the malady. The general condition must be treated: urotropin and salol were useful as urinary antiseptics; joint pains were much relieved by phenacetin or aspirin. Radiant heat, ionisation, and diathermy were also of use. The most valuable part of the treatment was the specific treatment, and that could be carried out by giving an autogenous vaccine, a small dose if it was advisable in an acute case, the doses being gradually increased at intervals of three or four days. In chronic cases large doses of a mixed vaccine were advisable. Vaccine therapy had been of great value in the treatment of gonorrhoea, but it must not be assumed that the more vaccine one gave the better the result. Sir William Willcox had recently seen a case of gonococcal arthritis of the hip in excruciating pain. The patient's doctor had been giving 6000 millions of gonococcus vaccine every day; when the vaccine was stopped relief immediately followed. After a few days vaccine treatment was recommenced, and pursued with moderation. Sensitised vaccines had been recommended, but the speaker

preferred to use the ordinary vaccines. Bier's treatment had also been used for the condition, a rubber band being placed on the proximal side of the joint for an hour or longer each day. Anti-gonococcal serum had been used for these cases, but the general opinion was that it was not of much value. Some authorities had tried all sorts of vaccines—even typhoid vaccine—for the disease. In late stages, when the arthritis and the acute symptoms had subsided, massage and passive movements to promote mobility of the joints were desirable.

The Factor of General Resistance.

Major A. T. FROST suggested that the medical man was practically helpless in the treatment of gonorrhoea; the patient's own resistance was the final element in the cure of the patient's disease. For example, 15 years ago a young officer in China got infected with gonorrhoea; when first seen by Major Frost six joints were infected, and the heart was involved. The temperature was 103° F. The patient was told to go home to England as quickly as possible, as the sea voyage might raise his resistance. At that date Major Frost felt afraid to use gonococcal vaccines. Three months after arrival in England the joints had cleared, and the heart showed no signs of disease. Major Frost agreed with Sir William Willcox that the best weapon against gonorrhoea was specific treatment by vaccines. He had seen a number of cases in which 1000 million gonococcal organisms were given, followed by a prolonged negative phase. It did not matter how small a dose was given at first; it could easily be increased rapidly until there were local signs that the vaccine was having some effect. In gonorrhoeal rheumatism one had to be careful not to increase the trouble by too large a dose early. In addition to protection by stock vaccines, autogenous vaccines made from the patient's particular strain, he thought, were of higher value. He supposed there was no case of gonorrhoeal rheumatism which had not got prostatitis, forming a natural store of vaccine, the man's own, untouched by heat or antiseptics, where the organism should be in the best state for treating the patient. The regular emptying of the prostatic focus by the finger and massage every five days was the best form of treatment. He wondered whether justice had been done by the bacteriologists who had been referred to in regard to the value of the complement-fixation test in the diagnosis of the nature of joint trouble. In the Military Hospital, Rochester Row, there had been excellent results from the method.

Major E. C. LAMBKIN said he had carried out a certain number of complement-fixation tests for gonorrhoea, and, like most workers, he found that in the acute and subacute stages the results were unsatisfactory. But when he applied to gonorrhoea the technique employed by Dr. A. L. Punch in complement-fixation tests against tubercle better results were obtained. Recently he had had some extraordinarily good results in chronic cases of vesiculitis and obscure joint conditions.

Dr. FOWLER WARD (Ipswich) said that during the later stage of the war he had a number of lorry drivers under his care who had gonorrhoea, and many of them had arthritis of an intractable kind. He concluded that this was because of the prostatic massage produced by riding on the hard lorry seat. He had air-cushions supplied to them, and from that time the relative number of arthritic cases was lower.

Dr. DENNIS VINRACE said that he had found great benefit from auto-vaccines prepared from discharge produced by gentle massage of the prostate. As one test of cure he passed a large metal bougie into the bladder, leaving it in position during the process of massage. Besides vaccines he had found internal treatment with salicylates, cinchona, or iodides effective where sepsis was present.

Dr. F. CARMINOW DOBLE said that at Rochester Row Hospital they had had nearly 5000 cases in four and a half years, of which 400 had joint complications. A complement-fixation test was done for every one, and over 80 per cent. showed a positive reaction.

The prostate or vesicles were affected in these cases, the prostate being boggy or the vesicles enlarged. The average time in hospital was under two months, and there were 12 cases of hyperkeratosis. One case nearly died; he was saved at the last moment by salvarsan in blood serum. With regard to treatment apart from vaccines, he found sulfarsenol in small doses intravenously (0.12, followed in two days by 0.18) acted like a charm. He had never given more than four injections, generally not more than three. Until the prostatic condition had cleared up, the patient could not expect to be fit.

Major G. PETT said Dr. C. A. Robinson, of St. Bartholomew's Hospital, had been treating cases of gonorrhoeal arthritis by diathermy; a certain number of the chronic cases cleared up quickly under this treatment.

Dr. A. C. ROXBURGH confirmed the statement of the last speaker that during the last three years all the cases of gonorrhoeal arthritis at St. Bartholomew's Hospital were sent to the electrical department for diathermy; in some the joints were involved, in some only the prostate. In acute cases the effects were remarkable, the joints lost their pain, and even when the condition had existed for months there seemed to be no means which acted so quickly.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Presentation of Medals.

THE annual general meeting of this Society was held at 11, Chandos-street, London, W., on June 21st. Sir PERCY BASSETT-SMITH was installed in the chair by the retiring President, Sir JAMES CANTLIE. The latter marked the close of his two years of office by presenting a handsome chain and enamelled badge to be worn by all future presidents of the Society in commemoration of his long association with the Society. The medallion bears the emblem of the Society, an anopheles mosquito, with a cinchona leaf, and is suspended from a gold chain comprising links bearing the names of past presidents of the Society.

The new President then made the first award of the Manson medal, founded in memory of the late Sir Patrick Manson, to Surgeon-General Sir DAVID BRUCE, and in doing so referred to the latter's past presidency of the Society and well-known achievements in the cause of humanity by his conquest of Malta fever and work on trypanosomiasis and tetanus. The first award was also made of the Chalmers Memorial Medal to M. EMILE ROUBAUD, of the Pasteur Institute of Paris, in recognition of his able researches in the domain of tropical medicine, and his distinction in helminthology and entomology. This medal was founded by Mrs. Chalmers for an original worker in tropical medicine or hygiene, of any nationality, and under 45 years of age.

Demonstrations.

Colonel CLAYTON LANE briefly described the application of his method of diagnosis of ankylostome infestation by the use of the ordinary centrifuge with buckets adapted to tubes measuring $\frac{1}{2}$ in. by $4\frac{1}{2}$ in. and containing a suspension of 1 c.cm. of stool in 18 c.cm. of concentrated salt solution. Centrifugation resulted in the flotation of all the contained ova to the surface and thus their collection in bulk greatly facilitated detection under the microscope.

Dr. NEVILLE SHARP showed slides exhibiting the differential staining of embryos of *F. bancrofti* and *Loa loa* (Kaduna) by means of immersion in dilute Giemsa's solution for 6 to 12 hours. The sheath of the former was stained a bright red and the nuclei, throughout the length of the embryo, a deep blue, in contrast to the uniform intenser blue of *Microf. loa* with its pallid V-shaped marking.

Dr. FABIAN HIRST read a paper on the

Spread of Plague in the East Indies.

illustrated by lantern slides, maps, and microscopical preparations of *Xenopsylla cheopis* and *Astia*, to show their destructive features and the presence of plague bacillus in the stomach of the former. The irregular distribution of the disease, as indicated by the plague map of India, and its main prevalence in the north and west, was partly dependent on conditions of humidity and lower temperature favourable to the survival of the rat flea most concerned in the spread of plague—viz., *X. cheopis*. The transport and storage of grain were also important factors by the food attraction offered to rats infested by *cheopis*—for plague was most rife where grain was grown and along the routes of grain traffic. Rothschild's differentiation of *X. cheopis* from *X. brasiliensis* and *X. astia* and the work of Martin and Bacot on the bionomics of the three types had rendered possible some explanation of the irregular distribution of plague in India, for this was found to coincide with the geographical distribution of the differentiated species of fleas. Reference was also made to the results of experimental infection of the rat-flea with plague-infected blood, which had shown that the mass of growth of plague bacilli developing in the flea's stomach led to "blocking" of the proventriculus and consequent starvation of the insect. *X. astia*, the species of flea infecting the rats of Madras, which district is relatively immune to plague, was readily susceptible to the effects of this obstruction, dying within 24 hours, whereas *X. cheopis*, when "blocked," made repeated attempts to go on sucking and was able to survive for several days or longer. Hence, *X. astia* was a less formidable vector than *X. cheopis*—the latter species, moreover, was incapable of thriving in the hot climate of Madras. Dr. Hirst drew attention to the fact that the Madras people subsisted largely on rice grown in the *astia* zone of the Presidency and were not dependent on imported grain. In Colombo, on the other hand, the shorter duration of the hot season enabled *cheopis* to survive and propagate in the cooler months. Its discovery on infected rats coincided with the outbreak of plague in Colombo in 1914, whereas previously *astia* only had been found among a large number of examined fleas. In Dr. Hirst's opinion, however, species distribution was probably not a factor of great importance in those parts of India where climatic conditions were specially favourable to the spread of plague by fleas. The prevalence of *astia* was a kind of meteorological indication that the climatic conditions were unfavourable to plague. The appearance of *cheopis* on rats, in localities where it was not indigenous, was to be regarded as a danger-signal. But by taking into account its distribution, and concentrating on the danger spots, considerable saving of effort in the prevention of the spread of plague might be effected. Dr. Hirst advocated the importance of paying attention to the destruction of the insect carrier in all its stages of development, no less than to measures against the rat itself, especially in the rat-proofing of grain stores and the more extended use of the cyanide process for disinfection of grain. He concluded by urging the need for further research into the habits and bionomics of rat-fleas and their reaction to plague infection.

Discussion.

The PRESIDENT said that in view of the important part played by entomological differences of the various species of rat-flea in influencing the distribution of plague, the proper protection of grain stores became a necessity.

Major W. A. JUSTICE, from his experience of plague in the Madras Presidency, laid emphasis on the main risk of infection to which Madras was exposed, coming by sea to the docks and not by rail. Communication by rail from the infected areas in the west was broken

in the transit from broad to narrow-gauge system, allowing of the escape of rats when the grain sacks were transferred from one railway system to the other. The time of harvest he regarded as having some influence on the outbreak of plague; in Calcutta district harvest at Christmas-time was followed by plague in February.

Colonel J. D. GRAHAM mentioned the difficulties attending the grain traffic in Mesopotamia associated with plague at Basra and Baghdad which called for special organisation and measures of disinfection on the river banks by the HCN process, particularly in dealing with grain coming from India.

Dr. HIRST, in his reply, emphasised the fact that in order to obtain reliable results as to the relationship of *X. astia* and *cheopis* respectively to the incidence of plague, it was necessary that the collection of rats for observation of their fleas should be made in cool weather when plague was prevalent.

MEDICO-LEGAL SOCIETY.

THE annual general meeting of this Society was held at 11, Chandos-street, London, W., on June 19th, Lord Justice ATKIN, the President, being in the chair. The President and officers were reappointed for the ensuing year.

Dr. A. S. WOODWARD read a paper entitled

SOME ATTEMPTS TO DEFRAUD LIFE ASSURANCE COMPANIES.

He said that prior to the passing of the Gambling Act in 1774 life assurance business was almost entirely of a speculative or gambling nature. In a book on this subject by John Francis, published in 1852, the prevalence of this form of gambling was vividly described. Walpole's life, for example, was insured by large numbers of people who had no interest in him whenever he came prominently in the public eye; when he became unpopular the premium required rose accordingly, and when he was threatened with impeachment the premium rose higher still. In fact, the percentage figure at which his life could be insured, which was publicly quoted in the papers, formed a fair index of his popularity. Again, after the '45 rebellion the lives of the Pretender and of members of his following captured and at large were insured by large numbers of persons who were naturally aggrieved when any of his following escaped capture or the death penalty. Even the grey hairs of Lord Lovat did not protect him from being the subject of this shocking form of gambling. And what must have been the feelings and effect on the health of a distinguished invalid when he read in the papers, alongside the bulletin of his medical attendant, that his life could only be insured by paying a premium of 90 per cent. This form of gambling was put down by the Act of 1774, which provided that insurance on the life of a third party could only legally be contracted when the person insuring had an interest in the life assured and that the capital sum payable was limited to the amount of such interest.

Frauds in more modern times were attempted by many means. Impersonation, or a mythical assurance, formed the basis of many attempted frauds. The three Bond brothers, of South Carolina, had employed this method with great success. The first brother, an insurance agent, insured the life of a mythical person with an assurance company; the second brother, a medical man, completed the medical forms and certified death at the appropriate moment. It was the business of the third brother to find a dead body, which then took the place of the mythical insured and was buried under his name. The whole business was staged effectively with an anxious female who was the wife of the insured and was run on very economical lines; one corpse was said to have done duty on five occasions. The Bond family was said to have made \$100,000 out of this business before the fraud was discovered. Forgery of the death certificate while the assured was

still alive was sometimes employed as a means of defrauding assurance societies, and "feigned death" was another. The latter form was employed in 1730 by a man associated with a woman who was able to fall voluntarily into a cataleptic state. This couple travelled from place to place; the woman was insured and apparently died; an empty coffin was buried, the man collected the sum payable and disappeared.

Medical misrepresentation might take the form of persons on the verge of death being certified as well for the purpose of effecting insurance. Mysterious disappearances were not uncommon during the late war; it is possible that some of them were intentional frauds upon insurance companies. An historical attempted fraud of this kind occurred in the case of Clement. When driving home one dark night followed by a friend (each in his own vehicle) Clement drove off the road where it ran alongside a river. The friend heard cries and found a dead horse and a broken vehicle but no sign of Clement, who was consequently presumed drowned. It was, however, discovered that the horse had been killed by a blow between the eyes and that footprints resembling Clement's led away from the river. The company was therefore able to contest the claim successfully. Suicide as a means of defrauding life assurance companies was not common nowadays as there was a clause in the policy which protected the company.

The Protection of Insurance Companies.

Insurance companies were protected in two ways, by the Act of 1774 (Geo. III.) already referred to, and by a further legal ruling that a man cannot insure "against the consequences of his own illegal act." In the case of life insurance the latter applies to legal homicide as well as to murder and suicide. Thus in the case of Fauntleroy, executed for felony after paying between 15 and 20 annual premiums, the company refused to pay the capital sum for which he was insured, and this refusal was upheld in the courts. In such cases, however, it lies with the company to prove "illegality." Another case of the kind occurred in the famous Maybrick case. Mrs. Maybrick was found guilty of the murder of her husband (who was insured for £2000) and sentenced to death, the sentence being later commuted to imprisonment for life. As payment for the expenses of her defence Mrs. Maybrick made over to her solicitors her interest in her husband's life assurance, but the policy was declared void. In the case of Monson, at whose trial on the charge of murdering the minor Ham-brough a verdict of "not proven" was brought in, the policy on the life of the victim was invalidated only on account of frauds in the answers to questions in the proposal form. Frauds upon life assurance companies might occur (1) in making the contract, (2) during the currency of the contract, and (3) in making the claim. The company obtained an idea of the physical risk by various means, so that the risk of fraud by one individual was reduced to a minimum. But the insuring office still stood a poor chance against a conspiracy by a group of individuals. "Breach of warranty," "non-disclosure" of important facts, and "false declaration" invalidated the policy. In 1828 a policy on the life of the Duke of Saxe Gotha was voided under curious circumstances involving "non-disclosure." The court physician answered all the questions on the proposal form; it was not suggested that any of the answers were inaccurate or misleading, but the physician did not state the facts of loss of speech and impaired mental faculties. As regards "false declaration" many cases could be quoted chiefly with regard to the answer to the question on temperance. Proposers often did not seem to be aware that in saying they were temperate they were warranting a fact and not merely expressing an opinion. Cases were on record where a man had said he was temperate, although at the time he was consuming 30 to 40 drinks a day and was actually on the verge of delirium tremens. Most companies now required an examination of the urine

which, in the case of male proposers, was to be passed in the presence of the physician. Proposers who knew they were suffering from albuminuria sometimes attempted to substitute another urine, but this attempt at fraud would be at once discovered as such urine was cold, unless precautions were taken to keep it warm. In one case of this latter kind the physician was astonished to find in the urine of a male proposer the large squamous epithelial cells characteristic of the vagina! The stated age of the proposer could nowadays be easily confirmed except in the case of persons born in Ireland, where before 1862 there was no regular registration of births.

Substitution was prevented by making the proposer sign the form in the presence of the medical examiner, although during the war certain aliens in the East End of London with obvious diseases did a thriving trade as substitutes for others called up for military service. After the risk had been accepted the proposer might increase the risk by going abroad to unhealthy countries or taking up a hazardous occupation, unless these added risks were expressly prohibited by the terms of the policy. Fraud in the certification of death was occasionally attempted, usually by representing to the medical attendant that the insured, who when last seen was ill, had died, and thus obtaining a certificate when, in fact, the assured was still alive. The time of death was occasionally of great importance in substantiating the claim or modifying the amount. Since the passing of the Friendly Societies Act in 1896 made it illegal to insure infants under 1 year for more than £6, and under 10 years for more than £10, the frauds of baby farmers had come to an end, and there was no obvious difference between the mortalities of insured and of non-insured infants.

Suicide was a legal felony and as such voided a life assurance policy, although in many cases the company was called upon to pay owing to a verdict of accident by a coroner's jury. In proof of this the Registrar-General's returns for a recent year were quoted. Thus while 375 fatal cases of poisoning were suicidal, 136 cases were found to be accidental, as were also 91 of 452 fatal cases of coal-gas poisoning, and 509 out of 669 fatal railway accidents.

The Protection of the Proposer.

The PRESIDENT remarked that life assurance companies were generally well protected by the formidable list of questions which the proposer had to answer before his life would be accepted for assurance. Indeed, it was rather the proposer who needed protection, and he suggested that in many cases the proposer would be well advised only to fill in the forms with the collaboration of his own medical and legal advisers. The worst offender in the history of frauds upon insurance societies was the infamous Dr. Palmer, who committed several murders, his victims including a brother and even, it was suspected, his mother. Monson escaped under a legal point at his trial. Hambrough as a minor could not legally make over the benefit of his life assurance to Mrs. Monson, and it was thought that Monson should have known this and realised that it could not profit him to murder Hambrough while the latter remained a minor. Frauds in modern times were almost confined to industrial societies, and in these cases the agent was often to blame for misrepresentation to the proposer. The agent was often aware of circumstances which would void the policy, but reassured the proposer in order to induce him to insure.

Mr. G. C. GARDINER referred to the unsatisfactory state of affairs which arose in connexion with the Workmen's Compensation Act; many cases of death from natural causes were alleged to be due to some accident long before death and in no way connected with it. Insurance companies would only be adequately protected when coroners obtained the services of an independent pathologist to perform post-mortem examinations, a practice which was

now increasingly common though not yet universal. The medical attendant of the deceased, practising in an industrial area, should not be called upon to perform the post-mortem examination, as it was difficult for him to form an unbiased judgment when he knew that a finding in favour of the insurance company might seriously prejudice his practice.

Dr. ROLAND BURROWS quoted the case of the aviator Hall, who was shot and killed by a woman named Baxter, to whom he had left his entire estate, including his life assurance. Baxter was, however, excluded from benefit by the legal ruling already quoted. A very pathetic case of suicide in an attempt to defraud insurance companies was that of a boy, aged 13 or 14, the son of a woman in very poor circumstances, who drowned himself at Southend after collecting and filling in the forms on all the weekly journals which offered life insurance to purchasers. This act of self-sacrifice was, of course, useless for the purpose for which it was intended, to relieve his mother financially. In his opinion it was the assured rather than the company which needed protection, as the company took every possible precaution. A High Court judgment against a company generally led to the addition of another question to the formidable list which a proposer had to answer.

Dr. A. S. MORLEY agreed with Mr. Gardiner as regards the propriety of coroners obtaining the services of an independent pathologist, and added that in the country coroners not infrequently found a verdict without any post-mortem examination. Dr. Morley gave instances of two unsuccessful attempts to defraud insurance companies. In the first of these a man who held an accident assurance policy converted the policy so as to cover total blindness. Six months later he claimed the benefit, £1000, for total blindness. The insurance company, however, discovered that he had been seen a few weeks before changing the policy by the late Sir V. Horsley and Dr. Beever, who diagnosed a pituitary tumour. It transpired that the assured's brother was an oculist who, knowing that blindness was an inevitable consequence of the tumour, had advised the change of policy. The policy was voided by "non-disclosure," but the company generously returned the premiums, feeling that blindness in itself was sufficient punishment. The second instance was that of a medical student in very poor circumstances who insured his life and then took to his bed; he called in a doctor, who found that he had albuminuria. The student became apparently very ill, and himself produced oedema of the legs by tying bandages around them before the doctor's visits. Finally he sent word to the doctor that he had died, and attempted thus to obtain a death certificate, which fortunately was withheld!

Dr. MORGAN narrated his personal experience with a life assurance society. As an officer of this society he was entitled to assurance without medical examination at a 15 per cent. reduction of premium. The list of questions he had to answer in the proposal form, however, compelled him to disclose the fact that he had been treated for some months at a sanatorium for supposed tuberculosis at the apex of the left lung. The lesion, whose existence even at that time was doubtful, had since given him no trouble and had in no way interfered with his health and ability to work. In spite of this the company required an examination by their principal medical officer, who "loaded" him, although quite unable to detect which apex had been suspected. Dr. Morgan's complaint was that, having been induced to apply for insurance under a misapprehension, he would have to disclose that he had been "loaded" should he now apply for life assurance to another company.

Dr. MONEY could not understand why the ordinary principle of "caveat emptor" should not apply to life assurance. The company ought to be satisfied with the results of the medical examination without asking the proposer to make disclosures which he might be tempted to conceal.

Dr. ATKINSON and Dr. H. BECKETT-OVERY also spoke, and Dr. WOODWARK replied briefly.

Reviews and Notices of Books.

DERMATOLOGY.

Entretiens dermatologiques. Série nouvelle. Premier volume. By R. SABOURAUD. Paris: Masson et Cie. 1922. Pp 334. Fr.11.

THOSE who are already acquainted with the work and writings of Dr. Sabouraud will not, perhaps, find much that is new to them in this volume. It consists of a series of clinical lectures, and may be divided into three parts, the first dealing with diseases of the scalp, the second with the diagnosis, ætiology, and treatment of a number of common dermatoses, and the third with acquired and congenital syphilis. No one certainly has done more to elucidate the ætiology of diseases of the skin than Dr. Sabouraud, and we owe, perhaps, more to him than to any other dermatologist alive or dead; much of his work needs revision, some of his conclusions are perhaps wrong, but most of his writings are based on acute clinical observation and the results of years of patient laboratory research, and they are already classical. In the opening chapter he recapitulates his views on the interrelation between the development and the diseases of the hair and the evolution of the sexual glands. It must be admitted that his theories, as well as his facts, are open to dispute. The former, which are very ingenious and probably in great part true, need not be argued, but it is misleading to say that "never after puberty can the scalp of the adult nor even of the adolescent contract ringworm," since several authentic cases of ringworm of the scalp acquired in adult life have been published. Again he states that pityriasis capitis—i.e., infection of the scalp with the bottle-bacillus—begins at early puberty, whereas it is frequently seen in infants and young children.

There is much common sense and practical advice contained in the chapters on the hygiene of the scalp in infancy and adolescence, and on trichoclasia, trichorrhexis nodosa, and trichoptilosis, and we commend them to the notice of hairdressers who pose as "hair specialists," since they will find therein exposed the fallacy of many of their pet theories. Apart from a rare idiopathic trichorrhexis nodosa of the moustache and of an equally rare form of trichoclasia, there is no doubt that Dr. Sabouraud is right in attributing these conditions to the mechanical effect of shampooing with strong alkaline soaps, shampoo powders, or ammonia, and to the use of hair dyes and curling-tongs. The popular process of permanent waving is justly condemned for the same reason. The use of a dusting powder containing sulphur and of a solution of sulphur in carbon bisulphide for the treatment of seborrhœa oleosa is described in detail. The powder is a convenient vehicle for sulphur, and for women is preferable to lotions and pomades. The carbon bisulphide solution is doubtless the most active preparation of sulphur we possess, and, in spite of its disadvantages, its employment according to the technique advised is the method of choice in severe cases of seborrhœa of the scalp and face in both sexes. Its smell is, of course, abominable, and its application is followed by a burning sensation which is distinctly painful, but the smell does not cling to the hair, and the pain lasts but a few minutes. Its advantages certainly outweigh its objectionable qualities, and we can testify to its value in obstinate cases of progressive seborrhœic alopecia in men.

English dermatologists will read with interest the chapter on the question of the seborrhœides. Dr. Sabouraud insists quite rightly that we must in the first place distinguish between pityriasis simplex, which is almost certainly due to infection with the bottle-bacillus, and seborrhœa, by which term is meant hypersecretion of sebum. The rôle played by the micro-bacillus in the latter state is still a matter of dispute, but in any case there is much to be said for the view that on the scalp pityriasis prepares the way for seborrhœa, whereas on the glabrous skin seborrhœa prepares the way for pityriasis. In his

account of streptococcal infections of the epidermis Dr. Sabouraud includes intertrigo, and for him true intertrigo is always streptococcal. For its treatment he advises painting with tincture of iodine diluted with ten parts of spirit, followed by the application of a zinc cream and dusting powder.

Two chapters are devoted to infection of the skin with the epidermophyton, particularly as regards its localisation on the hands and feet (eczematoid ringworm of the extremities). It is astonishing that no reference is made to the classical work of Dr. Whitfield on this subject. In 1892 Djellaludin Mouktar described ringworm of the palms and soles, but, according to Sabouraud, the infecting fungi in his cases were trichophytons, not the epidermophyton. In 1908 Dr. Whitfield pointed out that many so-called cases of intertriginous eczema of the toes were really due to ringworm infection. Two years later Sabouraud, presumably unaware of this discovery, published an article on the same subject, and demonstrated that the fungus was the epidermophyton. In 1911 the question was fully discussed at a meeting of the Dermatological Society of London, the openers of the discussion being Dr. Whitfield and Dr. Sabouraud. Yet the latter does not even mention Dr. Whitfield's name in this connexion, although reference is made to the discussion above mentioned; moreover, he refers to the benzoic acid ointment, which is known all over the world as "Whitfield's ointment," as having been "recently described by Pollitzer"!

Among the various other interesting subjects dealt with in the remaining chapters of this book, we may mention the use of baths containing an emulsion of oil of cade and chrysarobin in extensive cases of psoriasis as an alternative to the application of these substances in ointments, and the method of treatment, elaborated by Danysz, with injections of a vaccine prepared from faecal organisms. While admitting that the Danysz treatment is sometimes of no value in psoriasis, Dr. Sabouraud has seen good results from it in several cases. Sutton, in America, uses an autogenous *B. coli* vaccine as an adjuvant to local treatment with chrysarobin, and claims that he obtains more rapid and permanent results than with local measures alone. There is little doubt that the Danysz vaccine acts merely as a non-specific protein, but it is also often of undoubted value, if employed judiciously, in conditions other than psoriasis. A chapter on the treatment of furunculosis with staphylococcal vaccine is of peculiar interest to English dermatologists. A rapid method of preparing autogenous vaccine from cultures grown on a special medium devised by Noiré is described, and Dr. Sabouraud advises intramuscular injections twice a week. He claims brilliant results in furunculosis, but "when the staphylococcal infection is more superficial than in a boil, for example, in folliculitis, sycosis, and pyoderma, antistaphylococcal vaccination is without effect." The whole chapter illustrates how little vaccine therapy is understood in France.

Dr. Sabouraud closes his book with a section of ten chapters on syphilis; of these the most instructive are those dealing with hereditary disease and its clinical manifestations.

ENLARGEMENT OF THE PROSTATE.

Second edition. By JOHN B. DEEVER, M.D., LL.D., Sc.D., F.A.C.S.; Professor of Surgery, University of Pennsylvania. Assisted by LEON HERMAN, B.S., M.D., Assistant Surgeon to the Pennsylvania Hospital; Urologist to the Methodist Episcopal Hospital. Philadelphia: P. Blakiston's Son and Co.; London: John Bale, Sons and Danielsson, Ltd. 1923. Pp. 358. \$7.

THIS is a new edition of a well-known book written with the thoroughness characteristic of the author's other works. There is a systematic review of the history, anatomy, pathology, and ætiology of the disease, followed by an account of the clinical aspect which bears the impress of personal experience. Particularly useful are the author's remarks on the selection of cases for one and two stage operations. He

lays great stress upon the clinical examination of the condition of the heart and the blood. He uses the indigo-carmin test as frequently as the phenol-sulphonaphthalein test. Of this latter he insists that a low output of the dye, if unassociated with increase of the percentage of urea in the blood does not signify that removal of the prostate would be dangerous from the point of view of kidney failure. He considers a persistent low specific gravity of the urine as important as a low phenolphthalein excretion.

The author favours greatly the suprapubic operation and scarcely does justice to the real merits of perineal enucleation. Under certain circumstances, he advocates a partial operation. For median bar and bladder neck obstruction, he recommends open excision by the suprapubic route. There are some omissions which if remedied would make the monograph more useful. They are a consideration of the urea-concentration test of kidney function, the management of carcinoma of the prostate, and of those cases where a large diverticulum is associated with prostatic obstruction. This last serious complication is mentioned but is dismissed in a few lines.

THE PROBLEM OF POPULATION.

By HAROLD COX. London: Jonathan Cape. 1923. Pp. 198. 6s.

THIS volume deals with a thorny subject in a lucid manner, and those who hold differing views should consult it as an excellent exposition of the case for birth control. In successive chapters are discussed the arithmetic of the problem and its economics; there follow chapters on war and population, on social progress, on racial improvement, and on the ethics of birth control. In each of these chapters there is much debatable matter, and it is not surprising that acutely divergent views are being taken as to wise lines of action. The imperialist, desirous that the British Empire shall be peopled by those who will carry on the relatively high ideals of life of the Anglo-Saxon people, naturally deprecates the sterilisation of the sources of replenishment of Greater Britain; the economist, impressed with the close relationship between war and pressure of population, and between this and poverty, and having regard to the present unfavourably differential character of the reduction in the birth-rate is liable to desire ardently the widest knowledge of methods of contraception. In France also there is an increasing endorsement of Renan's striking words, referring to its declining birth-rate: "*La France se meurt; ne troublez pas son agonie.*"

Mr. Cox's somewhat crude statistics as to the relation between high birth-rate and high death-rate will need to be checked by the data now available in the Fertility Report of the Registrar-General. Nor are we completely convinced by the statistics as to the relation between excessive infant mortality and high birth-rate. The association is common, but not essential, as shown, for instance, by the remarkable experience of rural Ireland, with an extremely low rate of infant mortality and a standardised birth-rate which is perhaps the highest in Europe. Nor are we impressed with the picture of the evils of overcrowding in one increasingly urban population as a reason for birth control. It is not unlikely that the acme of this centripetal drive to towns has been reached; with the advent of gas engines and electricity, centrifugal influences are beginning to tell on our population. Meanwhile, the triumphs of social and sanitary progress are seen in the steadily increasing fall of the urban death-rate towards the level of that of rural districts. Mr. Cox quotes Dr. Brend's views as to the constant relation between dirtiness of air and high infant mortality. The facts are against any such relationship on a considerable scale. The problem of emigration has a close bearing on this question, and perhaps Mr. Cox underrates the effect of large-scale migration to Greater Britain on the prosperity of industrial England.

The teaching of the book on war is summed up in the conclusion that "the different races of the world must either agree to restrain their powers of increase, or must continue to prepare to fight one another," a statement which gives much food for thought. The same remark would apply to the sweeping statement that the enormous waste of infant life is the direct consequence of the reckless production of children. There was a vast saving of infant life before the birth-rate in this country declined, the continuing on a larger scale to the present time with a declining birth-rate. The last chapter on the ethics of birth control contains a very complete statement from the author's standpoint of the moral side of this problem; it deserves careful reading by those who are opposed to voluntary birth control in any circumstances.

LABORATORY MANUAL OF BIOLOGICAL CHEMISTRY.

Third edition. By OTTO FOLIN, Hamilton Kuhn Professor of Biological Chemistry in Harvard Medical School. London and New York: Appleton and Co. 1922. Pp. 300. 12s. 6d.

THIS excellent work, as might be expected, does not deal with general biochemistry, but more especially with such parts of it as bear directly on medicine and physiology. As a technician, Prof. Folin has no peer in any continent, and his quantitative methods, a joy to hand and eye, are nearly all described in the present volume, which will have a good European market on that account. New methods are described for the estimation of phosphates, sulphates, total base, sugar, and amino-acids in urine, and for chlorides and amino-acids in blood. Important improvements are also given in the methods for lipoids, uric acid, and sugar in blood. The sections devoted to the use of indicators are excellent, and have the advantage of not demanding a large number of elaborate solutions. The edition is a great improvement on the last one.

PHYSICAL CHEMISTRY.

Praktikum der Physikalischen Chemie. Insbesondere der Kolloidchemie für Mediziner und Biologen. Second edition. Von Dr. med. LEONOR MICHAELIS, A.O. Professor in the University of Berlin. Berlin: Julius Springer. 1922. Pp. 183. 5s.

THE sudden popularity of the long-neglected subject of physical chemistry has led to the exhaustion of the first edition in so short a time that the author could not undertake to re-write this book; the present edition is therefore simply a revised one, he tells us. The revisions are sufficiently extensive, however, to have made his apology rather superfluous. There have been added 23 new pages and eight new figures. We are not in the least surprised at the success of this little book, for, like everything from the pen of this distinguished writer, its contents are clearness itself. Prof. Michaelis has the gift, so rare among German authors and others, of saying exactly what he means in a few well-chosen words, and it is a pleasure to read him. The book contains 82 practical exercises on physical chemistry in its relations to biology and medicine. The chapters deal serially with enzymes, colloids, surface tension, diffusion and osmosis, swelling, viscosity and gelation, electrophoresis and electroendosmosis, adsorption, electromotive force, and the kinetics of reactions. The instructions are so clear, and the explanations so well-treated, that little preliminary knowledge of physical chemistry is needed to enable anyone with a good knowledge of general laboratory technique to go right through the course. The sections devoted to colloids, to the investigation of which the author has devoted so much of his own research, are, of course, excellent, and so are those dealing with the hydrogen-ion technique, of which we believe there is no better account in elementary language extant. In the present edition several new exercises dealing with the use of indicators for the determination of hydrogen-ions are included.

Reports and Analytical Records.

HYPOLOID INFUNDIN.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.1.)

THE Hypoloid Infundin-Pituitary Infundibular Extract (new standard) has been added by Messrs. Burroughs and Wellcome to their hypoloid brand products. It is a sterilised solution specially prepared for hypodermic injection and conforming to the standard recommended by the Medical Research Council and the United States Pharmacopœia. The strength is equivalent to a 10 per cent. extract, and the preparation has been found particularly useful in obstetric cases. The phials are supplied for use, under medical direction only, in hermetically sealed containers of 0.5 c.cm., the dose recommended as an ante-partum measure, and of 1 c.cm., being the normal post-partum dose.

LIPOCITHINE.

(MANSON'S [LONDON], LTD., 101, HATTON GARDEN, LONDON, E.C.1.)

This preparation is described as a synthesis of cholesterine and lecithine, and of greater efficiency than these two substances separately. The value of lipoids in therapeutics is well known, if their exhibition is carefully watched, and the manufacturers of lipocithine have obtained satisfactory medical verdicts upon the preparation, which is indicated as a restorative in many conditions of anæmia, asthenia, and prolonged convalescence. The formula is cholesterine 5 gr., cholesterine distearyl-glycerophosphate 5 gr., 100 gr. of pure and sterilised olive oil. The preparation is employed in gluteal injections and is supplied by Messrs. Douetteau, of Paris, through Manson's (London), Ltd. It clearly merits trial by the medical profession.

PHENOQUIN AND NEO-PHENOQUIN.

(SOUTHALL BROS. AND BARCLAY, LTD., BIRMINGHAM.)

These preparations of phenyl cinchoninic acid are described by the proprietors as uric acid eliminants. In its first form the remedy, which was introduced some five years ago, was found to be useful in gout, articular rheumatism, and the various indications of these conditions, while the introduction of lithium in the newer form of the preparation brought about rapidity of action. The drugs are supplied in tablets, and the usual accepted dosage in both cases is from 1 to 5 tablets twice daily—approximately 20 to 60 gr. The tablets should be given after meals, and in some cases 10 gr. of sodium bicarbonate in a tumbler of plain water taken simultaneously has been found useful.

STANDARD LACTOSE.

(THE BRITISH DRUG HOUSES, LTD., GRAHAM-STREET, LONDON, N.1.)

Lactose of a uniformly reliable quality is in regular demand for biological purposes, and a duly tested standard preparation will be welcomed by many workers. "Standard" lactose has been tested with the following organisms in sterile peptone solution: *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, *B. enteritidis* gaertner (no fermentation), and *B. coli* communis, *B. coli* communior, *B. cloacæ* (fermentation with acid and gas). With 1 per cent. of Standard Lactose B.D.H. the reactions of *B. typhosus*, *B. paratyphosus* A and B, and *B. gaertner* are constant after 96 hours' incubation; the reactions of the *B. coli* organisms and *B. cloacæ* are obtained in 12 hours.

ADRENALIN "CIBA"; DIDIAL; DIALACETIN.

(THE CLAYTON ANILINE CO., LTD., 68½, UPPER THAMES-STREET, E.C.4.)

This is a synthetic preparation of adrenalin in which care has been taken that the product should be pure and stable. Neither in crystals nor in solution does any deterioration occur, a fact which is of particular

service to the dentist who does not frequently require to use adrenalin, while adrenalin "Ciba" is considerably cheaper than the natural product.

From the same firm we have received two new preparations or derivatives of Dial, which we have previously noted in THE LANCET as a powerful hypnotic, less toxic than veronal, and producing no unpleasant after-effects. Dial has been used in general practice, and especially among mental patients as a hypnotic, as it restores the sleep habit effectively and allows of gradual reduction of dosage.

Dialacetin is a combination of Dial in association with an analgesic. It has been used by French physicians as a sedative, especially in epilepsy, and its employment has been made the subject of considerable discussion in the French press. This new hypnotic sedative might well be tried in insomnia associated with neuralgic pains.

BOWEN'S OLD INVALID PORT.

(W. H. CHAPLIN AND CO., LTD., 48, MARK-LANE, LONDON, E.C.3.)

This wine, shipped from Oporto, when analysed was found to have the composition:—

	Per cent. by volume.
Alcohol	19.6
Total sugars	7.9
Consisting of—(dextrose	3.25
(levulose	4.65
Sugar-free extractives—	
Glycerol, &c.	1.4
Fixed acid as tartaric	0.36
Volatile acid as acetic	0.05
Mineral matter	0.21
Water	71.1
Preservatives (salicylic acid, sulphites, boric acid) and dye-stuffs absent.	

The evidence afforded by this analysis indicates that it is a true "port," confirmation in this respect being the preponderance of levulose over dextrose. It has a full, agreeable palate and bouquet, and is well matured.

STERILISED SURGICAL DRESSINGS.

(SQUIRE AND SONS, LTD., 413, OXFORD-STREET, W.1.)

We have received from Messrs. Squire and Sons a specimen drum containing sterilised surgical and accouchement dressings. All the dressings have been carefully made in the first instance, and have been sterilised with the fullest precautions. The modern plant installed for this purpose subjects the dressings to moist heat at a temperature of 126° C. for 30 minutes, and the dressings are issued in hermetically sealed containers or drums. The sterilisation chamber is fitted internally with a patent mechanical arrangement, whereby the drums are hermetically sealed inside the chamber while still in a perfectly sterile atmosphere. This ensures an absolutely aseptic condition of the contents from the time of sterilisation until the drums are opened for use. The outfits and dressings comprise everything needed either to complete an outfit or to supply a full one. No stress need be laid upon the obvious importance of being able to obtain with a feeling of perfect security and at any hour of the day and night such an outfit. It should be noted that, as a partial vacuum exists in the drum, at a low temperature further contraction of the rarefied air may lead to indentation in the tin. A series of bacteriological experiments have been made by the Clinical Research Association to test the efficiency of sterilisation. Various cuttings were taken from the contents of one of the drums and inoculated under aseptic precautions into sterile fluid media, when no growth of organisms took place after 48 hours' incubation at 37° C. under aerobic or anaerobic conditions. Further, infected swabs were placed in the centre of one of the drums containing dressings, overalls, &c., and having been submitted to the sterilising process were inoculated into culture-media, when no growth of organisms was obtained during the same time and at the same temperature. But a duplicate set of control swabs gave rich growths of the respective organisms. The sterilising process is thus demonstrated as thoroughly efficient.

THE LANCET.

LONDON: SATURDAY, JUNE 30, 1923.

THE LAW OF CORONERS.

DURING 1922 the Government was understood to be preparing a Bill for consolidating and amending the law of coroners. In August an official spokesman expressed the pious hope that it might be produced before Christmas. The Bill has never appeared, but, so long as proposals for amending the existing law are being actively canvassed, projects for consolidating that law may reasonably be delayed. There are, indeed, many points at which the law relating to coroners invites amendment. There is the profitless duplication of certain proceedings in magistrates' and coroners' courts. The Home Secretary stated a year ago that the Government Bill would deal with this point. He also undertook to consider the extension of the provisions of the City of London Fire Inquests Act of 1888 (as recommended in Dr. WALDO's annual report for the year 1921), and the insertion of a clause making the viewing of the body by a jury optional, subject to the discretion of the coroner to insist upon it. Mention of the jury recalls the fact that at present the war-time provision as to the composition of coroners' juries is being respite by inclusion in the Expiring Laws Act: permanent legislation should not be postponed indefinitely by this hand-to-mouth method. The power to increase the remuneration of coroners which Parliament sanctioned in July, 1921, was another example—though a belated one—of legislation due to the war. If only some scale for remunerating coroners could be satisfactorily determined on a basis which excluded the number of inquests, it would kill the unworthy accusation that coroners multiply inquests for the sake of fees.

Perhaps the most important proposals for amending coroners' law relate to death certification and the disposal of bodies, the object being to lessen the risk of premature burial and to make it more difficult for crime and foul play to escape detection. "It is no fault of the law," reported a Departmental Committee in 1901, "if premature burials do not take place: the present law of death certification offers every facility for the concealment of crime." In this connexion two private Members' Bills are now before the House of Commons, though their progress is slow. The first of these is Dr. SALTER's Deaths Registration and Burials Bill, with its interesting proposals for the registration of still-births in a separate register book, and for the appointment, somewhat on the French model, of "public certifiers of death"—i.e., registered medical practitioners who will have to attend inquests if the coroner finds that no other doctor will be present, and whose duty it will be to give a death certificate when the deceased has not been professionally attended during his last illness. The other Bill is Major MOLLOY's Coroners' Law and Death Certification (Amendment) Bill, supported by Colonel FREMANTLE and Dr. WATTS. This Bill originally proposed (though the clause is not likely to be pressed) that local authorities should appoint "special medical officers" in each coroner's district to view bodies and give a death certificate when no registered medical

practitioner is available for that purpose, and to investigate and report to the coroner upon the cause of death. Of the two Bills Major MOLLOY's seems to stand the better chance of success, especially if it incorporates various suggestions made by the Special Committee on Death Certification of the Federation of Medical and Allied Services—a committee which represented all the interests concerned. The Bill thus modified would reduce the time-limit for notifying death to the registrar (under Section 10 of the 1874 Act) from five days to two. It forbids the disposal or embalming of human remains except under the authority of a certificate or coroner's order, and prohibits the inclusion of more than one body in a grave unless notice is given to the registrar. The main safeguards against foul play are briefly these: no burial without a certificate of registration of death; no certificate of registration of death without a medical certificate; every medical certificate to declare the fact of death and the cause of death on a distinctive form of which the counterfoil will be numbered and recorded so that every form issued can be traced. The registrar's certificate is to be endorsed with various details of the date, place, and mode of disposal of the remains. The resultant records may produce some useful statistics, especially if the effort to standardise the classification of diseases succeeds. Other clauses of the Bill provide that the registrar who is informed of a death but has not received a certificate of the cause of death shall inform the coroner; a dead body is not to be retained in a house longer than seven days unless under authority of a justice or coroner where there is reasonable doubt of death having occurred; within 24 hours of the expiration of that period the occupier must remove the body for disposal or apply to the medical officer of health, whose duty it will be to bury the remains within 24 hours.

On a cursory examination these proposals seem a great improvement upon the old law. As they need not involve either vast expense or an army of new officials, there seems no sufficient reason for suggesting that the new law should be made adoptive or that it should be at first confined experimentally to urban areas.

TUBERCLE ANTIGENS.

WE called attention a fortnight ago to Prof. G. DREYER's lecture at the St. Mary's Institute of Pathology and Research in which he related some striking successes, experimental and clinical, attained by the use of defatted bacterial vaccines. A very favourable impression has been created by the evidence brought forward that in three guinea-pigs infected with tubercle bacilli of human type the course of the disease was stayed by injections of defatted antigen. Guinea-pig proof has long been demanded by the sceptic as the sign from heaven without which he would not believe. We learn that the Medical Research Council are now arranging, in consultation with Prof. DREYER—who by a happy fortuity had just become a member of the Council—for extensive trials at various centres where facilities can be provided, the vaccine being distributed from the Oxford School of Pathology. The results so far communicated to the Research Council have been favourable almost without exception, and although a cautious attitude is enjoined until a longer period has elapsed, nevertheless, in cases of tuberculous disease of the glands and of the skin, it can be said already that the results of this treatment have

surpassed any known to have been attained regularly by other methods. Encouraging results have also been gained in the treatment of septic infections, particularly puerperal fever.

The success of the Dreyer tubercle antigen, if it should prove as serviceable in other hands, will be, like the Toronto work on insulin, the keystone of long and patient search in many lands. From the early work of KOCH onwards the structure and chemical composition of the tubercle bacillus have been the subject of ceaseless investigation, and the information available has already been exploited on therapeutic lines with a certain degree of success. As long ago as 1910, Prof. G. DEYCKE and Prof. HANS MUCH showed that the tubercle bacillus consists of several chemically distinct substances, to each of which they believed the human body reacts in a specific manner. They treated tubercle bacilli with dilute lactic acid and separated two antigens, one soluble in water, the other insoluble. The latter residue can be split into an albumin group, a fatty acid and lipoid group, and a neutral fat and fatty alcohol group. Their partial antigen or partigen system of treatment was based on the assumption that the body reacts to each of these partial antigens with a specific antibody. If the value of the Deycke-Much teachings were to be gauged simply by the volume of the writings on the subject, no one could fail to be impressed, but the criticisms of such authorities as Prof. UHLENHUTH have sown distrust, and the opinions of many clinicians of experience are unfavourable to the Deycke-Much school. Since 1910 there have been many other attempts to rob the tubercle bacillus of its acid-fast coat, and in 1918 a paper was published by DOSTAL and SAHLER¹ whose new vaccine, "tebecin," was said to be obtained from a pure culture of tubercle bacilli grown on glycerine media to which a saponin had been added. In the fifth generation the bacilli were found to have lost their acid-fastness, and it was claimed that they were not only non-pathogenic to experimental animals, but were capable of conferring on guinea-pigs immunity to virulent tubercle bacilli. The results obtained in human tuberculosis with "tebecin" were said to be excellent, and it was claimed that neither a focal nor a general reaction was provoked. Later reports of this vaccine have, on the whole, been favourable.

A more novel method of attacking tuberculosis, set out² by Dr. A.-R. JENTZER, Dr. MARKOVIC, and Dr. RASKIN before the Geneva Medical Society in January last, also centres on the fact that the tubercle bacillus has a waxy, fatty, protective coat. But while other workers have attacked this coat in vitro, the Geneva method is to attack it in vivo. Their thesis is, in brief, that the leucocytes, the lymphocytes in particular, contain ferments capable of destroying the sheath of the tubercle bacillus, and that the more lymphocytes can be stimulated to produce such ferments, the more unhappy will be the lot of the tubercle bacillus in the tissues. Several interesting observations are quoted in support of this thesis. The larva of the caterpillar which invades beehives has a remarkable capacity for digesting wax and is also, incidentally, immune to the tubercle bacillus, an emulsion of which is promptly disposed of by this larva (*Galeria melonella*) on subcutaneous injection. In half an hour the bacilli are absorbed by the larva's phagocytes, and in a few hours they cease to be acid-fast. Dr. JENTZER and his colleagues have worked with a compound of fats, lipoids, and waxes sold by the

Swiss firm of Hausmann as "gamelan." It is given by subcutaneous injection or inunction, and the claim is made that it stimulates the tissues to produce ferments which not only saponify the fatty and waxy substances introduced by parenteral injection, but also the fatty, lipoid, and waxy constituents of the tubercle bacillus. "Gamelan" has been tested on guinea-pigs infected with tubercle bacilli before and after the administration of this remedy, and the experimental evidence thus obtained is, on the whole, encouraging. The clinical evidence is also in its favour, and it is claimed that in about 70 per cent. of the cases of tuberculosis in human beings treated by "gamelan," there was an increase of the number of the lymphocytes. There were also many signs of clinical improvement, and this was achieved without the discomforts of a local or general reaction. The exact composition and mode of manufacture of "gamelan" is not published, and till further confirmation of the claims made on its behalf is forthcoming, it would be well to treat this remedy with the reserve commonly shown by the medical profession towards secret remedies.

It must, however, be obvious that if Prof. DREYER'S discoveries have been to a certain extent anticipated, but kept secret, by persons anxious to exploit them commercially, his own candid publication is in harmony with the tradition which has never been better set forth than in Prof. SODDY'S words:—

"... Let it not be forgotten that science is a communism, neither theoretical nor on paper, but actual and in practice. The results of those who labour in the fields of knowledge for its own sake are published freely and pooled in the general stock for the benefit of all. Common ownership of all its acquisitions is the breath of its life. Secrecy or individualism of any kind would destroy its fertility."

The storehouse of medical knowledge is being notably enriched in these latter days by the spread of this tradition which is bringing about the more complete internationalising of medicine.

THE CAUSE OF DEATH.

THE pathologist who honestly confronts the problems presented to him in the course of his routine work will be the first to acknowledge the limitations of the ordinary post-mortem examination. The gross lesions of such diseases as pneumonia, tuberculosis, nephritis, or cancer are obvious enough to admit of a diagnosis being made from a naked-eye examination, though, it may be noted in passing, the actual immediate cause of death may be far from easy to determine. In many diseases, however, the morbid changes are apparently slight and often quite inadequate to explain the patient's death. A very large proportion of such cases may be made clear by careful histological and bacteriological examinations, and the more attention that is paid to these subsidiary but all-important investigations, the less frequently will the pathologist have to confess himself baffled.

In a highly suggestive paper on unexpected death, which appears in the present issue of THE LANCET, Prof. E. E. GLYNN and Mr. R. C. DUN describe the elucidation of six obscure cases in which a simple post-mortem examination alone would have failed to provide the true explanation of death. Apart from the intrinsic interest of the cases detailed therein, this paper is of value in that it raises general questions of great importance. One of them is the standing of the condition known as status lymphaticus. It is not

¹ Wien. klin. Woch., 1918, No. 14.

² Schweiz. med. Woch., May 3rd and 10th, 1923.

going too far to say that the unwarrantable use of this term, especially in coroners' courts, during the last decade or so has caused such a reaction that man, pathologists refuse to admit the existence of such a condition, at least as a pathological entity. It is certain, at any rate, that a hyperplasia of lymphadenoid tissue exists in a large proportion of perfectly healthy children. An unprejudiced examination of the bodies of children killed, say, in street accidents commonly reveals a more or less advanced state of lymphatism; and unless we are to regard this as an indication that the lymphatic child is less alert than other children, and therefore less able to cope with the exigencies of our modern mechanical traffic, it is difficult to attach any particular significance to it. Another and more important point raised is the trustworthiness of the medical evidence given in the coroner's court. There is no doubt that the authors are correct in questioning its value. All the circumstances militate against an accurate and painstaking examination of many of the difficult and obscure cases which come within the coroner's jurisdiction. And even granted a sympathetic attitude on the part of the jury and the court officials, it must be remembered that the modest fee which the law allows the expert witness can in no way repay him for the labour involved in elaborate investigations, or the time spent in the second attendance at the court which the adjournment of an inquest entails.

Finally, the perusal of this paper makes it difficult for the critical reader to retain much faith in that part of the Registrar-General's reports which deals with the causes of death, for on what are his figures based? If the post-mortem room, unaided by the laboratory, can only provide him with the truth in a certain number of cases, upon what proportion of ordinary death certificates, uncontrolled even by a cursory autopsy, is he justified in placing any reliance at all? It is an interesting mathematical problem, this, with which the statistician has to wrestle.

INTERNATIONAL POST-GRADUATE FELLOWSHIPS.

A FURTHER opportunity for the mental refreshment offered by study of different methods of work is announced. The Rockefeller Foundation of New York, whose generosity and vision seem equally wide, have entrusted the Medical Research Council with a fund to be used in providing Fellowships in medicine in the United States. Fellowships will be awarded by the Council, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the United Kingdom. It is understood that similar medical Fellowships provided by the Rockefeller Foundation will be awarded by the National Research Council at Washington to American graduates desiring to work for a time at selected centres of research work in this country. A Fellowship will have the value of not less than £315 a year for a single Fellow, or £470 for a married Fellow, payable monthly in advance. Travelling expenses and some other allowances will be made in addition. A Fellowship will be tenable for one year, which will, as a rule, begin in September. Applications for Fellowships tenable for the academic year 1923-24 shall be made not later than July 20th next. Full particulars and forms of application are obtainable from the secretary, Medical Research Council, 15, York Buildings, Adelphi, London, W.C. 2.

Annotations.

"Ne quid nimis."

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE report for 1922 of the Council of the London and Counties Medical Protection Society, presented by Sir John Rose Bradford, President, at the annual meeting on June 20th, showed that the Society's thirtieth year of existence had been attended by progress and success. The number of applications from members asking for advice and assistance was 645, as compared with 465 for the year 1921. In the great majority of cases satisfactory results were obtained without litigation, and the results of cases where litigation occurred were in the main gratifying. The Society's provision for indemnifying members against costs of the other side and damages in unsuccessful cases continued to work smoothly and well. In view of the Society's increasing work and growing membership, a long lease was secured of convenient offices at Victory House, Leicester-square, W.C. 2, with the additional use of a large room for meetings of the Council or of the Society. With a view to encouraging young practitioners to join the Society as soon as they begin practice, the Council decided not to charge an entrance fee to candidates applying for membership of the Society within a year of the date on which their names are entered on the Medical or Dentists Register. After very careful consideration the Council resolved, for the present at all events, not to elect as members any dentists who do not possess a registered degree or diploma. A standing joint committee of the Medical Defence Union and of the London and Counties Medical Protection Society has been elected for the purpose of considering matters affecting both organisations. The report contains the usual array of cases dealt with by the Society to the satisfaction of both parties; in a section devoted to charges of negligence or unskillfulness the following warning paragraph is inserted:—

"The treatment of fractured bones gives rise to many claims for damages every year, and members are strongly advised to insist as early as possible upon an X ray examination in all cases where a fracture or dislocation has been, or may have been, sustained. When this is refused, or omitted, for any reason, a member should provide himself with clear evidence—preferably in writing—to prove that he was not responsible for the neglect or omission."

With reference to libel and slander, members are strongly urged to refer all such difficulties to the Society before dealing with them in any other way. Among replies to questions of medical ethics raised by members, was one informing a doctor that it was quite proper to send out a circular notice to his patients informing them of his change of address, provided every care were taken that only his patients received the notice and that it was limited to the intimation of change of address. Complaints are occasionally received concerning alleged touting for patients—especially panel patients—by collectors employed by the doctors concerned.

"Such touting is probably not often directly authorised by their employers, but when collectors are paid a commission on the receipts there is an obvious inducement to make efforts to extend their employer's practice and consequently an inducement to carry on touting even though the employer is known to disapprove of it."

Members are therefore strongly advised not to make such arrangements. With regard to medical witnesses at coroner's inquests, the report points out that while many coroners are scrupulously just, some coroners, and more coroners' juries, treat medical witnesses and medical evidence in a manner neither considerate nor just; it also points out that "riders" to verdicts of coroner's juries have no legal value, and are often unjustly defamatory opinions expressed in an irregular way under the protection of privilege. Dental members of the Society are stated to apply for

advice and assistance to about the same extent proportionately as medical members; claims for damage on account of alleged negligence and want of skill form one of the largest class of cases. Litigation has frequently been avoided by the Society's advice or mediation.

PITUITARY EXTRACT AND INSULIN.

CUSHING and his collaborators in 1910 found that in cases in which there existed in the organism a hypophyseal deficiency, whether this occurred clinically or was produced experimentally, there was "an acquired high tolerance for sugars, with the resultant accumulation of fat," whilst the blood became hypoglycæmic. Since then many investigations have been made on the effect of infundibular extract on normal blood-sugar. Dr. J. H. Burn records in the *Journal of Physiology* (vol. lvii., No. 5) certain experiments made on unanæsthetised rabbits, samples of blood having been obtained from the ear vein. Determinations of the level of the blood-sugar were in all cases made on 1 c.cm. blood by the method of Shaffer and Hartmann; this method is substantially the same as Maclean's method, recently described in our columns, although the latter as modified requires only 0.2 c.cm. of blood for a determination. It was found that subcutaneous injections of extract of posterior lobe of the pituitary gland, given simultaneously with injections of insulin, diminish or abolish the fall of blood-sugar produced by the latter. The doses of pituitary extract used do not, when given alone, produce a rise of blood-sugar sufficient to explain this inhibition of the action of insulin, as the result of an algebraic sum. The effect is not produced by similar extracts of anterior lobe of pituitary, or of spleen, thyroid, brain, or thymus, nor is it produced by histamine. The property in the case of posterior lobe extract is destroyed by normal alkali in the cold. Pituitary extract removes the symptoms of hypoglycæmic convulsions, causing a rapid elevation of the blood-sugar. The effect of a small dose of insulin is greatly increased by previous intravenous injection of ergotoxin. Confirmation is given of the following points: (a) Pituitary extract inhibits adrenalin hyperglycæmia and glycosuria; (b) ergotoxin abolishes adrenalin hyperglycæmia and glycosuria; (c) insulin greatly reduces the hyperglycæmic action of adrenalin. Experiments are described in which subcutaneous injections of pituitary extract in the normal animal led to a fall of blood-sugar, though as a rule such injections cause a transient rise. Dr. Burn further discusses the difficulty of fitting all of the preceding results into a consistent scheme, a difficulty which he has not at present been able to overcome.

BUSACCA'S REACTION IN TUBERCULOSIS.

THIS reaction, based on the observations of Busacca in Vienna in 1921 that the tuberculous are specially sensitive to normal horse serum, has not hitherto attracted much attention in this country. It may be therefore of interest to note that the subject has been recently taken up by Dr. G. Montemartini¹ of the Institute of Surgical Pathology in the University of Rome, who practised the reaction in 315 cases consisting of the following groups: healthy subjects, 30; anæmic subjects in tuberculous families, 43; pulmonary tuberculosis, 174; tuberculosis of the glands and serous cavities, 39; osseous tuberculosis, 29. He injected intradermally 0.2 to 0.3 c.cm. of normal horse serum into one forearm and simultaneously practised von Pirquet's cuti-reaction on the other, using Koch's old tuberculin diluted to 25 per cent. A larger dose than 0.2-0.3 c.cm. should not be used as it may provoke a traumatic reaction. Of these reactions 57 per cent. of Pirquet and 59 per cent. of Busacca were positive. In normal individuals 6 per cent. were positive, while in the others, including the predisposed cases, the positive results varied from 47 per cent. to 74 per cent., the lower figure being that

of chronic and the higher of early and rapid tuberculosis. The total positive reactions including predisposed individuals and those suffering from various forms of tuberculosis were 65 per cent. According to ages, 25 per cent. of positive results were obtained in those under 4 years of age, and as many as 76 per cent. in those between 50 and 80. In the few breast-fed infants the reaction was invariably negative. The high positive percentage in the old was attributable to the fact that the patients were mostly old tuberculous cases collected from sanatoriums and had calcified lesions. These observations of Dr. Montemartini tend to show that an organism which has become allergic owing to a tuberculous infection reacts also to non-specific stimuli, and the greater the allergy the greater is the susceptibility to other stimuli. X rays and solar radiation also are non-specific stimuli which act like the proteins. The specificity of the tuberculin reaction is therefore relative and certainly inferior to that of true antigen reactions. The larger number of positive results being met with in tuberculosis of rapid course and not long duration, while a negative result was usually obtained in those of two or three years' duration, suggests that the reaction has a prognostic as well as a diagnostic significance. The reaction described by Busacca is non-specific, but has the same significance as the specific reaction of Pirquet, denoting a tuberculous infection more or less intense, latent, or circumscribed.

COMFORTS IN HOSPITAL.

IN view of recent proposals¹ for the use under certain conditions of beds in general hospitals by the middle classes, the regulations governing the introduction of supplementary food into the wards of various hospitals become of especial interest. It is useless to disguise the fact that the delicacies with which the middle-class patient is tempted to eat during convalescence can hardly be supplied in general hospitals. A questionnaire was sent recently to 24 important general hospitals, selected in approximately equal numbers from those in London on the one hand, and those in large towns throughout the country on the other. The secretaries were asked what regulations for the introduction of (1) eggs, (2) butter, (3) fruit, (4) sweets or chocolates, by patients' friends were applied irrespective of whether an individual patient might or might not be allowed to have one or other of these foodstuffs on medical grounds. In addition, it was asked what was the rule with respect to questions on the telephone about the welfare of patients, and what were the visiting hours for the friends of patients other than those on the danger list. Any provision whereby a patient considered to be dying might be allowed luxuries in the way of foodstuffs not usually permitted was inquired into, and finally it was asked whether these regulations applied to any private paying wards that might exist in the hospital. Eighteen replies have been received and present features of interest. Sixteen hospitals—that is, all but two of those who have replied—allow fruit as well as butter and eggs to be introduced, mostly at the discretion of the sister of the ward, in some cases at the discretion of the medical officer in charge of the ward. The remaining two allow butter and eggs to be introduced, under these conditions, but, somewhat inexplicably, have a rigid rule forbidding fruit. Consistently enough, these hospitals also veto the introduction of sweets, but of the 16 previously mentioned 11 allow sweets also. In certain hospitals it is stated that any foodstuffs approved by the medical officer of the ward may be imported. It would be interesting to learn whether this permission includes uncooked choice food, such as chickens or soles, or even cold dishes prepared with affectionate care at the patient's home. Six hospitals allow inquiries to be made by telephone; one arranges for each ward to be connected to the main telephone

¹ La Riforma Medica, xxxix., May 7th, 1923.

¹ Vide "British Hospitals Association: Some Administrative Problems," THE LANCET, June 9th, 1923, p. 1197.

service in order that such facilities may be easy to provide; another has two officers whose whole time is given up to answering inquiries. Others again allow inquiries over the telephone in cases of urgency only, and six announce that they discourage the use of the telephone for inquiries, though they do not state, as do three of the hospitals, that no replies will be given under any circumstances. In most cases there are no private wards in the hospitals interrogated, but in one only of those that have private wards are there any different regulations for these wards, the difference consisting in the extension of visiting hours from twice a week to every afternoon. Visiting hours are, for the most part, one or two hours twice or thrice weekly.

It is obvious that each hospital has its own problems, and that its geographical position and the general circumstances of the majority of its patients must make a difference to its regulations. We would not presume to offer criticism or advice as to the details which have so courteously been supplied to us except on one point only. It is a time-honoured custom for friends of the sick to supply fruit for their delectation, and in many cases grapes or oranges are longed for by patients. Since it has been found in 16 of the 18 hospitals which have replied to our questionnaire that the general permission to introduce fruit under the supervision of the medical officer or sister in charge of the ward leads to no ill-results, we would plead, not only on behalf of the potential middle-class patient, but of the hospital-class patient with generous friends, that a modification of the rigid rule to exclude fruit under all circumstances whatever might lead to considerable alleviation of suffering, and would doubtless earn the gratitude of those patients who have memories of other hospitals where this boon is accorded. In this case, indeed, the little more, how much it is, the little less, what worlds away.

THE EARLY DIAGNOSIS OF PLUMBISM.

In October, 1919, plumbism was included in France among the liabilities of employers and workmen's compensation insurance agencies, and this step has added to the importance attached to this vocational risk. In a previous publication Dr. A. Feil and Dr. R. Heim de Balsac¹ pointed out that the most early and delicate laboratory tests for plumbism were the demonstration of lead in the urine and of basophil granules in the red corpuscles. In a later paper² they admit that the demonstration of lead in the urine is a tedious and difficult task, and that though it is comparatively easy to find the basophil granules of lead poisoning in red corpuscles, laboratory apparatus is needed, and this is not always to hand. In this country, it may be remarked, these granules are not considered diagnostic of plumbism, as they may occur in any trouble which causes anaemia by destroying red cells. The French authors have, therefore, attempted to discover early pathognomonic clinical signs of plumbism, and with this object they have carried out wholesale examinations of employees in factories in which lead was used. In one factory, turning out accumulators, 96 apparently healthy employees were examined, and in another group of cases examined there were 83 workers employed in motor-car factories turning out painted coach work. Among the first group of 96 employees there were 88 who had worked with lead for less than five years, and only eight had been exposed to lead poisoning for a longer period. In the second group of 83 employees there were as many as 53 who had worked with lead for more than five years. Although these workers were apparently healthy, the lead line was found in 65 per cent., being well marked in 25 per cent. and slight in 40 per cent. A history of lead colic was obtained in 5 to 6 per cent., and only in 3 per cent. was a history of parotitis obtained. Other symptoms and signs such as myalgia, arthralgia, high arterial pressure, and a taste of lead

did not occur with sufficient frequency or uniformity to be characteristic. As for the lead line, it is certainly frequent even in an early stage. But though it shows that the person concerned is exposed to lead poisoning, it does not necessarily imply that this person is actually suffering from lead poisoning. It may be that the lead has become deposited in the gums from the surface of the mouth and not from the blood-stream. On the other hand, there may be no lead line in persons actually suffering from lead poisoning, passing lead in the urine, and showing basophil granules in the red blood corpuscles. Indeed, there may be the most profound lead poisoning without any lead line in the gums. The conclusion to which the authors of these papers are driven is that however tedious and difficult the laboratory diagnosis of plumbism may be, it is only by the two tests already referred to that early and accurate information can be obtained as to the existence of plumbism. The authors are apparently unaware that more lead is excreted by the bowel than by the kidney. The lead line and other clinical signs of early disease may be suggestive, but they are neither uniform nor reliable, and the lead line may, perhaps, lead to the unnecessary abandonment of remunerative employment.

FIFTY-FIFTY SALICYLIC OINTMENT.

At the close of the last meeting of the Section of Dermatology held at the Royal Society of Medicine on June 21st, Sir Archdall Reid read a brief communication on "a new method of treating skin diseases." This method is apparently a simple one, consisting merely of the application of equal parts of salicylic acid and vaseline. This ointment has, it is claimed, been used with striking success in lupus vulgaris, scabies, and particularly in acute eczematous dermatitis. It is also being used for the treatment of tinea tonsurans, in which disease, it is said, the application of the ointment is followed by degeneration of spores which can be recognised microscopically. Dr. V. J. Blake, who spoke in favour of the method, admitted that he was still sceptical as to its curative powers in ringworm of the scalp, but stated that the results up to date were more promising than any that he had obtained with other ointments. He was impressed with the rapidity of its effect in eczematous dermatitis, even in acute cases. A number of patients were shown in which the method had been used with good effect. In one, however, which was demonstrated as having been cured of extensive lupus vulgaris, the diagnosis was palpably wrong, as no trace of scarring was visible. To attempt to estimate the value of this method of treatment is obviously impossible without a personal trial, but a few comments are justifiable. It is unlikely ever to be widely adopted in scabies, however efficient it may be, since the classical treatment with sulphur ointment, if properly carried out, is so rapidly successful and very much cheaper; presumably at least 4 oz. of salicylic acid ($\frac{1}{2}$ lb. of the ointment) would be required to effect a cure in a single case. In lupus vulgaris the value of a 25 to 50 per cent. salicylic plaster (with or without creosote) has been recognised for many years, and the well-known Beiersdorf plaster of creosote and salicylic acid is widely used, particularly in lupus verrucosus. It is probable that the plaster is more potent than the ointment. On theoretical grounds it is very unlikely that the salicylic ointment would be really efficacious in the treatment of ringworm of the scalp (unless it produced suppuration in the hair follicles, and this, judging from the cases seen, it does not appear to do), the reason being that ointments will not penetrate sufficiently deeply into the follicles to destroy the fungus in the lower part of the infected hair. New methods of treating tinea tonsurans are continually being published, but none of them seem to convince the expert dermatologist of their efficacy, and epilation with the X rays still remains the method of choice in the vast majority of cases. On the other hand, it is possible that Sir Archdall Reid's ointment may prove of real value in

¹ Bulletin Médical, March 18th, 1922.

² Paris Médical, May 26th, 1923.

certain cases of eczematous dermatitis and of pyogenic infections of the skin. There is nothing new, of course, in the use of salicylic acid for the seborrhœic forms of eczema, for chronic eczema of the palms and soles, and for eczematoid ringworm; for the last-mentioned disease a saturated solution of salicylic acid in spirit is habitually used in the tropics. But if the claims put forward for the 50 per cent. ointment in acute eczema be established it may be that Sir Archdall Reid has made a valuable addition to the local treatment of this condition, and doubtless his method will be given a thorough trial.

THE CONCENTRATED ARC FOR CHRONIC ECZEMA.

A REPORT by Dr. Svend Lomholt,¹ of the Finsen Institute in Copenhagen, appears to warrant the belief that in many cases of chronic eczema which have proved refractory to the more conventional methods of treatment, concentrated carbon arc-light may effect a rapid recovery. Dr. Lomholt describes his results as remarkable, and this claim is evidently justified. Hitherto about 40 cases of chronic eczema have thus been treated, each exposure to an ordinary Finsen lamp of 50 ampères lasting for about 15 minutes. In most cases one or two exposures were given to each eczematous area, but in a few cases three exposures were necessary. In a large number the disease was of long duration and belonged to the type generally labelled as neurodermatitis. Many other methods of treatment had proved futile in most of these cases, and repeated exposures to the X rays had not achieved the desired object. But though the disease had often proved refractory to treatment for several years, a practically complete cure was effected by the carbon arc-light in almost every case. Itching and other symptoms disappeared, as well as such signs as scaling, lichenisation, and hyperkeratosis. Some slight pigmentation and hyperæmia remained after the reaction had disappeared, and the reaction itself resembled that of a slight burn. Only in a few cases was the reaction severe enough to yield vesicles and to lead to the loss of the most superficial layers of the skin. The results were not quite so good or uniform when the eczema was comparatively acute or "weeping." But even among these cases many good results were achieved. There are certain drawbacks to this treatment; it is somewhat tiring and expensive, and only a comparatively small area can be treated at one exposure. It would seem, therefore, that at present, at any rate, this treatment should be confined, as a rule, to cases which have proved refractory to other treatment. The fact that this treatment is most suitable for chronic and refractory cases is in itself the best testimony to its efficacy; when a new treatment is introduced for some disease which has not been amenable to older methods of treatment, it is seldom that the advocates of the new treatment single out the most chronic and obstinate forms of the disease on which to demonstrate their claims.

HYGIENE OF CREW-SPACES.

Dr. J. Howard-Jones, medical officer of health to the Newport (Mon.) Port Sanitary Authority, observes in his annual report for 1922 that the Board of Trade regulations controlling the hygiene of crew-spaces have not yet been revised, in spite of the fact that much greater attention has been devoted to the subject by other maritime nations in recent years than by Great Britain. The lighting regulations are not enforced and crew-spaces are often very dark, while what spaces are available for the accommodation of the men are often not used to the best advantage. Dr. Howard-Jones finds that, generally, much greater attention is paid to the comfort and sanitary requirements of the crew on foreign-owned than on British vessels of the same date

of construction. Among the thousands of ships that visit every year the port of Newport the specific defects most frequently found are as follows: defective lighting; dull-coloured paints which reflect little light and darken the already dismal quarters; defective ventilation, while at the same time the smells from store-rooms for oils, ropes, and paints and from dirty cable lockers are insufficiently excluded; dampness from leaks or from sweating of the bare iron on the ship's side. Sometimes there are no tables or seats for the men in the crew-spaces, which are their dining-rooms. The water-closets are badly placed and inconsiderately planned; they are often filthy iron troughs, ranging from 3 to 9 feet in length, with outlet direct through the vessel's side, without storm valves to prevent backwash of contents, thus fouling the unfortunate users in rough weather. The closets, besides, are often but imperfectly ventilated, with inadequate provision for flushing and cleansing. As we read this report, we recall that two years ago the town council of Newport¹ adopted a resolution affirming that the time was ripe for a revision of conditions of accommodation for seamen in the merchant service, and urged that a strong committee should be set up, representing the Board of Trade, the Ministry of Health, shipowners, shipbuilders, the officers and men of the merchant service, port sanitary authorities, and the Admiralty, to arrange that revision. Nothing was done then or since. The time is now ripe to return to the subject and to press for a revision of regulations, for though shipbuilding is now slack, its revival is surely imminent. If the regulations are not revised before that revival is upon us, the bad conditions of lodging for the men of the merchant marine may be stereotyped for another decade. From unnecessary hardships and even miseries at sea we beg the Board of Trade to deliver the British seaman.

CRANIAL ENDOTHELIOMATA.

ACCORDING to Dr. Wilder G. Penfield,² of New York, formerly Beit Memorial Research Fellow at the National Hospital for Paralysed and Epileptic, there is a group of dural endotheliomata which are manifested by a typical, slowly growing, hard prominence in the cranium. Examination of the records of 420 patients at the National Hospital who had been proved to have brain tumours at operation, on autopsy showed ten examples of this kind, in each of which the intracranial tumour was situated immediately beneath the prominence. Dr. Penfield has also collected nine similar cases from medical literature, including those which French writers have named hemicraniosis, in the belief that they were hypertrophies invariably situated in the cutaneous distribution of the first division of the trigeminal nerve. In Dr. Penfield's series of ten cases all the patients had noticed an increasing lump on the cranial vault before admission. In four cases it had been the first sign of anything wrong, and in two the enlargement was not noticed until the onset of the first symptoms. In seven cases the first symptom was pain which was usually most intense beneath the cranial boss. In two cases the first symptom was an epileptoid seizure, and in one case there was no mention of early symptoms. The symptoms following pain are due to encroachment on the cerebrum. Epileptoid seizures are common. There may be hemiplegia or symptoms of increased intracranial pressure, according to the situation and size of the tumour. The frontal bone is the most frequently affected, but the temporal or parietal bone may also be the seat of the new growth. The ages of the patients ranged from 18 to 60. Of 17 cases in whom the sex was stated, 5 were women and 12 men. Microscopical examination of endothelioma of the dura shows that it arises from the arachnoid or inner surface of the dura mater, through which it passes in a number of places and enters the overlying bone,

¹ Acta Dermato-Venereologica, vol. iii., Fasc. 3-4.

causing a complete rearrangement of the osseous structure. The bone-forming elements are caused to lay down bone in the substance of the neoplasm, the osteogenesis being greatest in the portion of the tumour between the skull and the scalp. In most cases it should be possible to diagnose the condition before the onset of the distressing cerebral symptoms. The cranial prominence, with stabbing pain beneath the tumour, is pathognomonic. Operative removal in cases where the patient has survived the immediate effects results in cure.

PRIMITIVE SEMICIRCULAR CANALS.

A VERY important place among primitive vertebrates is occupied by *Osteolepis*, which, indeed, is described by Prof. D. M. S. Watson as the oldest known bony vertebrate. It was an active predatory fish, whose fossilised remains are found in the Devonian stratum. An early gnathostome, it is to be classed among the crossopterygian ganoids, and hence is perhaps to be placed nearer the line of tetrapod descent than are some other early ganoids. It is, therefore, a matter of no little interest to find that, as Prof. Watson showed so clearly at the summer meeting of the Anatomical Society last week, the semicircular canals of this very early fish were essentially of the type which we are accustomed to associate with higher development, both in number and arrangement. It would seem to follow from this fact that in all likelihood the conditions such as are found in the hagfishes, where only one or two canals are present, are not to be looked upon as primitive—as has been the usual custom—but as secondarily acquired. This view, however, implying the loss of important functions in active animals, is harder to comprehend than the simultaneous development of the three canals, an objection stressed by some of the members of the society. Whatever may turn out to be the opinion ultimately accepted on the present-day structures in the myxinoids, the interest of the demonstration of the actual canals in position, by Prof. Watson, is very great, and its bearing on the settlement of the questions is evident.

DEATH OF THE PHYSICIANS' BEDELL.

By the death of Mr. William Fleming, which took place on June 20th, the Royal College of Physicians of London loses a very tried and trusted servant. Mr. Fleming was appointed Bedell in 1892, and held that office until his death. Before his appointment as Bedell he had been in the service of the College in other capacities for some 20 years, partly at the College itself, partly as head clerk at the Examination Hall, and had risen from small beginnings to a highly responsible post. The duties of Bedell embraced also those of general secretary, and from long and assiduous service and study he had acquired an unrivalled and detailed knowledge of the affairs of the College, both past and present, and a deep veneration for the College itself. His industry was unflagging and his courtesy to all comers unflinching. He will be greatly missed.

FELLOWS of the Royal College of Surgeons of England who have not yet voted are reminded that the election of members of the Council will take place on Thursday, July 5th, and that their votes should be sent in before 2 P.M. on that day.

THE Royal Society and the Medical Research Council have agreed jointly to receive delegates from the "British Empire Cancer Campaign" to discuss the formation of a scientific committee for the distribution of money subscribed to the Campaign for research purposes and the revision of the Articles of Association of the Campaign which may be necessary to give effective powers to the committee. Representatives of the Imperial Cancer Research Fund will be present at this conference.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXVI.

THE TREATMENT OF CYCLIC VOMITING.

THE treatment of cyclic vomiting, acetonæmic vomiting as it is sometimes called, is far from satisfactory, but I venture to think that our failures would be less frequent if the importance of some of the details of treatment were more fully appreciated. The symptoms of this condition are usually well defined and the clinical picture originally described by Gee under the name of "fitful or recurrent vomiting of children" is now well recognised. A child usually under the age of 12 years has bouts of vomiting which have generally begun during the first four years of life, sometimes in the first year. The bouts last for some days, occasionally as long as a week or ten days, and during the greater part of this time nothing is kept down, not even water. They recur at varying intervals; some children have them only two or three times a year, others have them every month or six weeks. Premonitory symptoms occur in some cases for 48 hours or less before the vomiting begins. Perhaps the commonest of these is an access of peevishness and contrariness; in several of my cases an unusual increase of appetite was noticed for one or two days before each attack; in a few the first indication of the coming attack has been the smell of acetone in the breath. Often, however, the vomiting begins without warning and very quickly becomes severe, so that the child is sick every half hour or even every ten minutes for several hours, bringing up bilious or blood-streaked vomit. Gradually the intervals become longer and perhaps after two or three days there is vomiting only three or four times a day.

With the vomiting are associated other symptoms; drowsiness is a feature in most cases. The breath has generally the smell of acetone, and deep sighing respiration is often a noticeable feature. There is usually no fever, or at most the temperature reaches about 100° F., but there are exceptional cases with considerable fever. There is almost always constipation and the stools are often pale in colour during the attack. A trace of albumin is frequently present in the urine, in addition to the acetone which is generally present by the time the vomiting begins and sometimes before. As the attack goes on the abdomen becomes more and more empty and carinated, the eyes sunken, the voice feeble or hoarse, and in a severe case the vessels of the conjunctiva are injected. The lips and tongue are dry, and though even water is vomited, the child, distressed with thirst, craves drink. In the worst cases I have seen delirium and in fatal cases coma. As the child grows older the attacks tend to become less frequent and I have seldom seen any after the age of 12 years; amongst 100 consecutive cases I found only three cases at 13-14 years, in which the attacks were still occurring, one case at 15½ years. It is, however, not right merely to comfort the parents with the assurance that the child will grow out of the condition, for not only do the attacks interfere with the child's progress, physical and educational, but they also entail some risk to life. I must have seen altogether some 150 children with cyclic vomiting and amongst these were 3 fatal cases, and a brother of one of these three had also died in an attack. Clearly it is worth while to take stringent measures, and, moreover, experience shows that more can be done in the way of prevention than of arrest.

Preventive Treatment.

Dietetic.—It has been recognised that the intake of fat in the diet plays an important part in the production of acetonæmic vomiting, but there is one fat which seems to be specially liable to excite the attacks—

namely, milk-fat. I want to lay stress upon this factor, for if it were more generally recognised many of the children who suffer with cyclic vomiting might at least have the number and severity of their attacks reduced. As it is many a child with this condition has his trouble aggravated by well-meaning but wholly mischievous treatment. When the vomiting at length ceases the child is left weak, wasted, and hollow-eyed. The mother then, either of her own initiative or sometimes by her doctor's advice, proceeds to "feed the child up," especially with "plenty of milk," and as likely as not, with cream also. The natural but unrecognised result is a gradual reaccumulation of the toxic condition, so that another attack occurs and on recovery the child is once more stuffed with milk and so the trouble goes on. I would lay it down as the first essential in the preventive treatment of cyclic vomiting that milk is to be reduced to a minimum, and that cream is to be avoided altogether. The amount of milk which can be tolerated by such children varies, but there are few who can safely take more than half a pint per diem, and there are many who will do best if the total amount of milk allowed daily is not more than 5 oz. I have seen cases in which the attacks recurred until milk was excluded altogether. If milk is allowed it must not be a rich milk, such as that of Jersey cows or some special "nursery milk"; a skimmed milk, skimmed by machinery so as to contain extremely little fat, may be useful both for drinking and for milk puddings. Cream must be forbidden. Sometimes after attacks have long been absent a recurrence has been due to a small amount of cream given as a treat. Butter seems to be better tolerated but should be used sparingly. Other fats have not seemed to me to be nearly so liable to excite attacks, nevertheless, since any fat given too liberally may have this effect, they must be used with caution. There is no reason to curtail sugars and starches. Sugar, indeed, has some special value for these children, but chocolate has seemed to me to provoke attacks; if the child is to be allowed sweets, it is well to specify plain candy sugar or barley sugar.

Drugs.—Next in value to dietetic treatment in the prevention of cyclic vomiting is the regular administration of bicarbonate of soda. This should be given in doses of about 20 gr. twice daily to a child of 3-7 years and of about 25-30 gr. to older children; in certain cases it is necessary to give it three times daily. Inasmuch as the drug has to be given regularly over a long period, perhaps two or three years, it is often convenient to order it in the dry form. The mother may be told to dissolve as much as can be piled on a shilling, which is about 18 gr., or on a florin, which is about 24 gr., in three tablespoonfuls of cold water for each dose. If hot water is used so that the bicarbonate is more easily dissolved, the bulk of fluid to be taken can be reduced. There is rarely any difficulty in getting children to take this solution; syrup can be added if desired. In cases which do not respond well to treatment with the simple bicarbonate of soda, the salt should be dissolved in a 10 per cent. solution of glucose instead of in water, for there is reason to believe that glucose has some special value in correcting the perverted chemistry of ketosis.

Regulation of Bowels.—Not only must the bowels be kept working every day, but the efficiency of the measures already mentioned seems to be increased by a regular weekly dose of some mercurial aperient, in dose sufficient to secure a thorough evacuation but not to purge; grey powder, about 2 gr., is usually suitable.

If these measures are carefully carried out the attacks of cyclic vomiting are usually greatly reduced in number and severity, and in some cases prevented altogether—so long as the treatment is continued. It is well to impress this last point on the parents; the rigid observance of the diet restrictions and the daily dosing with bicarbonate of soda and the weekly grey powder have to be continued possibly for two or three years. It is difficult to say when it is safe to relax the treatment. I have an impression that in the case of children from 2-7 years old it is advisable to allow a longer interval of freedom from attacks before discontinuing treatment than in older children, but

certainly in either case there should be at least a year entirely free from attacks before any relaxation of treatment is allowed, and even after this interval the result of such relaxation is sometimes a speedy relapse.

Treatment During Attacks.

Treatment in the attack must be directed towards two objects: (1) to counteract the toxic effect of ketosis, (2) to maintain the strength of the child. For the former purpose it is necessary to introduce as quickly as possible and in as large amount as possible some alkali; sodium bicarbonate is generally used. As it cannot be retained by stomach it must be given by rectum, and well diluted, for a large dose has to be used and it is probable that less rapid absorption takes place when a concentrated solution is administered. One drachm of sodium bicarbonate should be given in 3 oz. of water, and after three or four of these injections have been given at intervals of four hours, it may be well to substitute alternate injections of 6 per cent. glucose. Enemata are generally well retained during the attack, and the larger the amount of fluid which can be introduced this way the better. Usually nothing is retained when given by the mouth, but teaspoonful doses of the solution of bicarbonate of soda in 10 per cent. glucose or in barley-water may, at least, comfort the child, who is usually distressed by thirst. It is useless to attempt giving any other food, even broth or meat juice, by mouth; indeed, often this seems to provoke anew the violence of the vomiting. For the maintenance of the child's strength we have to rely almost entirely on rectal administration, and nothing is more valuable than the glucose solution already mentioned with a drachm or more of brandy added if necessary. In the most severe cases, when vomiting has been continued for several days, it is sometimes necessary to use subcutaneous infusions either of normal saline or of a 5 per cent. dextrose solution.

The Arrest of Vomiting.—I have left till last measures for the arrest of vomiting in the attack, for, apart from the rectal administration of sodium bicarbonate, it is doubtful whether anything is effective. Certainly none of the drugs ordinarily used for vomiting of gastric origin, such as bismuth, iodine, or dilute hydrocyanic acid, have the slightest effect, nor have local applications to the epigastrium. Hypodermic injection of morphia—1/30-1/20 gr. for a child of 4-8 years—seems to diminish the vomiting in some cases, but in most the vomiting once started runs its course uninfluenced by treatment. When vomiting has ceased for about 12 hours feeding by mouth may be begun cautiously, and I think broth and sweet jelly, and then rusk or toast and weak tea, or small quantities of Horlick's malted milk, make a good beginning; from this the child can usually within a day or two progress to ordinary diet, care being taken to avoid more than the prescribed allowance of milk.

Special Articles.

SOJOURNERS IN THE TROPICS.*

BY ANDREW BALFOUR, C.B., C.M.G., M.D.,
F.R.C.P. EDIN.,

DIRECTOR-IN-CHIEF, WELLCOME BUREAU OF SCIENTIFIC
RESEARCH, LONDON.

THE title of this lecture is intended to indicate that the white race, *under existing circumstances*, cannot be looked upon as more than wayfarers in the tropics, as people who have there no continuing city in the sense that they can settle and rear a progeny blessed with the energy and virility which characterise, let us say, the Northern European or the inhabitants of the Northern United States. Fresh interest was imparted to this subject when Huntington published in 1915 his fascinating and suggestive work "Civilisation and Climate," a book which, unhappy in the time of its birth, is not sufficiently well known, and deserves to be studied by all concerned with what is certainly an imperial aspect of the public health. Speaking generally, what Huntington really set himself to do was to determine how much truth exists in the old, if somewhat impolite, adage which, indeed, he quotes: "No one is worth a tinker's damn on whom the snow does not fall."

The world is his oyster and in prising into it he goes far beyond the limits of our present inquiry, but he touches upon the question of the white man in the tropics again and again, and appears to throw fresh light upon a problem which has vexed men since the days of Aristotle. There is no need, however, to hark back to the time when the ancient Greeks argued as to the effect of climate on mankind for, like Huntington, they were concerned chiefly with its influence on the higher civilisation. This the American author regards as including the power of initiative, the capacity for formulating new ideas and for carrying them into effect, the power of self-control, a high standard of honesty and morality, the power to lead and to control other races, the capacity for disseminating ideas. These and similar qualities he says, find expression in high ideals, respect for law, inventiveness, ability to develop philosophical systems, stability and honesty of government, a highly developed system of education, the capacity to dominate the less civilised parts of the world, and the ability to carry out far-reaching enterprises covering long periods of time and great areas of the earth's surface.

THE WEST INDIES.

A much simpler question, which must take precedence—namely, the question as to whether the white man can preserve his health in a hot climate like that of Jamaica—was answered by Charles Leslie in 1739, who says: "The general complaint which is made of the Unhealthiness of this Place is founded upon a perfect mistake. If New-comers would preserve a due Regimen and live temperately, they might be as happy here as anywhere in the World." Like Sir Hans Sloane before him and Lady Nugent after him, he makes it only too evident that the white residents in Jamaica—the men at least—too often, by their copious libations, washed themselves into graves which they had dug with their own teeth. As the racy old Lady Nugent wrote, "they eat like cormorants and drink like porpoises." The latter part of her simile may be erroneous, zoologically speaking, but her meaning is very clear.

Now this little side-light on Jamaica in the olden days recalls the fact that the problem which faces us is a complex one. In other words, the effects of climate are inextricably mixed with those of other factors:

economic, social, religious, historical, dietetic, and, most important of all, medical. If we confine ourselves to the tropics we shall find that it is almost impossible to eliminate the disease factor, especially malaria. It is true that Barbados is not plagued with paludism, but there ankylostomiasis is present, and hence its "poor white" problem cannot be studied to advantage. At the same time the facts are interesting. The "poor whites" in that colony, as in Grenada and Jamaica, are in a good many cases descendants of people who had blue blood in their veins, and who were sent out as political prisoners to labour as bondsmen on the plantations. A goodly number, though by no means all, are of pure European descent. Although, as Watts and Nicholls maintain, there are doubtless many native whites quite healthy and capable of work, the race, as a whole, has degenerated, or perhaps we should say its adult representatives are degenerates, for the children when quite young are often most attractive and appear intelligent. I have rarely seen such beautiful examples of childhood as two "poor white" bairns I found ill with enteric fever in the hospital at St. Johns, Barbados. Incidentally, I would, as once before, advance a plea on behalf of the children of these "poor whites." Will no one save them from the degradation which assuredly awaits each succeeding generation? In Barbados they soon pick up the hookworm with its inevitable concomitants, at least if the infestation be severe, of bodily sloth, stunted growth, and mental hebetude. In Grenada they get both ankylostomiasis and malaria, and in both islands they too often take to drink and acquire venereal disease. Poverty has them in its grip, and they are despised even by the negroes, who jeer at them as "Red Legs." It is a sad business, but one wonders how much is really due to climate alone. As I say, the offspring of these poor whites frequently look very different from their parents. It would be instructive, as well as humane, to remove them at an early age from their surroundings and to see how they would develop in a favourable environment. Here is good work for some philanthropic millionaire.

The island rock of Saba, one of the Lesser Antilles, is said by Hintze, a cautious writer with 15 years' experience in various parts of the tropics, to afford a better example of the persistence of a healthy white race in a hot climate, for it is free from any great prevalence of disease. I have only seen Saba from the sea. It is a Dutch island and was settled by white men in 1640. The race has remained pure, and the people, stated to be intelligent, are chiefly farmers and sailors. The women are said to be the handsomest in the West Indies, and to be distinguished by their slimmest and healthy appearance. Such signs of degeneration as exist—insanity and idiocy in one village—are attributed to inbreeding. This question of inbreeding is always one of the disturbing factors which are cropping up. It has, so far as I know, never been scientifically studied in the case of existing settlements in the tropics, and there is a great deal of vague generalisation as to the harm it produces. Yet the late Sir Armand Ruffer, in his careful studies on the palæopathology of Egypt, did not find that the consanguineous marriages in the royal families of ancient Egypt produced any dire effects upon the offspring born of them. On the contrary, speaking of the Ptolemies, he says: "The children from these incestuous marriages displayed no lack of mental energy. Both men and women were equally strong, capable, intelligent, and wicked." Here, too, there was a much closer inbreeding than ever occurred in a place like Saba. The conditions on this island appear to prove Hintze's case that it is not necessarily the climate which is at fault in most tropical countries, but the concomitants. At the same time, the evidence leaves something to be desired.

According to Dr. Boecke, the blonde and blue-eyed white fisher folk in the neighbouring island of St. Martin are a healthy and vigorous stock. They also date back to the middle of the seventeenth century. Like the inhabitants of Saba, they have been in contact with negroes, but appear to have bred true and to have maintained their European characteristics. Another

island worthy of consideration is Curaçao. When there early in 1914 I noticed how sturdy and well conditioned many of the white settlers, both male and female, were, and was not surprised to find that Hintze, quoting van Blom, states that these traders and planters, who have been there for many generations, are accounted healthy and vigorous. At the same time Curaçao is quite unlike most of the other West Indies. It is a dry, bare place, reputed very salubrious, and more like a chip of one of the more barren parts of South Africa dumped down in the Caribbean, than a typical tropical island. Moreover, it is kept very clean by the enterprising Dutch, and presents a surprising contrast to the neighbouring mainland of Venezuela.

THE EAST INDIES.

Turning now to another part of the world, we find that what obtains upon the island of Kisar, or Kissa, is always advanced as proof positive that the descendants of Europeans, who for generations have been restricted to tropical conditions, need not succumb to the influence of their surroundings. Attention was first directed to the inhabitants by MacMillan Brown in his work "The Dutch East," wherein he wrote:—

"In 1665 eight Dutch soldiers were sent by the Netherlands East India Company to the little island of Kissa, 16 miles off the most easterly point of Timor; a fort was built and they were told to watch the Portuguese. The Company forgot all about this lonely outpost, and Sergeant Kaffyn and his men realised that they were, in fact, marooned. They had their wives with them; a guiding principle of the Dutch East India Company. They set to work to build houses and cultivate the land. The descendants of these eight couples still remain. They have been wonderfully fertile; in the two and a half centuries the 16 have risen to 300, and they are a sturdy race with no signs of any evil effects from interbreeding. They still keep their blood pure and still have big families, and many have fair European faces and complexions and many children have light hair and blue eyes. These people had to work, and work hard, and the consequence is that after 250 years in this tropical island they are still fertile, indeed prolific, and still keep their North European characteristics."

According to Prof. Brown, many of the settlers are pure Dutch, and I gathered from his book that the island they inhabit is naturally dry, and hence presumably healthy. The little colony has, however, been visited recently by Dr. Elkington, who has made a fairly complete study of the conditions obtaining. His inquiries, embodied in his paper "The Mestizos of Kisar, Dutch East Indies," though strengthening rather than controverting the main argument, brought to light certain facts which should be stated, as it appears that Prof. Brown's account of the little colony requires considerable modification. Indeed, Dr. Elkington, who is Chief Quarantine Officer for the North-Eastern Division of the Commonwealth of Australia, speaks of it as a romantic tale. His own account of the history of the settlement may be summed up briefly as follows:—

At various dates between 1783 and 1819 there came to Kisar as soldiers or officials nine men of Dutch origin who took to themselves wives. Of these five married women of Dutch blood like themselves and four married women who were more or less tinged with coloured blood. None of the families date back further than the last quarter of the eighteenth century at earliest. In 1819 the Dutch East India Company decided to withdraw from Kisar the little garrison of soldiers and officials which had been posted there for over a hundred years previously. All the European families except these nine, and probably three or four others of originally European name who had become almost indistinguishably submerged in the native population, thereupon left the island.

At the time of the withdrawal of the Dutch garrison the coloured population of Kisar numbered at least several thousands. At the present day it comprises some 9000 people. There was very little inter-marrying between the European community and the natives, but it would seem that Europeans did wed persons of mixed origin, a point of some little importance. For some 60 years after 1819 the community was practically forgotten and unvisited. The island, a dry, unattractive place, is not readily accessible from the sea. When rediscovered, as it were, in the "eighties" of last century, the European community had greatly

degenerated, both physically and mentally, had relapsed into heathenism, and had lost the Dutch language. The Dutch Government set out to rescue and to elevate them and, as will be seen, has in large measure succeeded. Some were transferred to Koepang (Dutch Timor) and a few went elsewhere. Now there are about 200 at Kisar and 100 at Koepang. Dr. Elkington, who visited both Koepang and Kisar in 1921, describes a third of this special community as having fair hair, blue eyes, fair complexions and skin, and distinctly European features and build. Even in those families and individuals showing considerable intermixture with native blood, the European type of features persists. Apparently the children are for the most part mentally alert. There is said to be no mediocrity amongst them. They react to education either very well or very poorly. The majority do well. A medical examination conducted at Kisar in 1904 showed the Mestizo children of that day to be mentally backward and physically degenerated, but Dr. Elkington found no obvious sign of physical degeneration at the time of his visit. Six out of 20 children examined had enlarged spleens due to malaria. He suggested the desirability of applying a series of Binet-Simon or Porteus tests for mental reaction and of undertaking an examination for hookworm. It may be said that the people weave cloth, make chairs, breed goats, cultivate maize, vegetables, and fruit, and catch fish. Their homes are of the native type, but are clean and well kept, and possess a little European furniture. Dr. Elkington's conclusions are as follows:—

1. That nine families of originally North European or mixed North European and native blood have persisted on Kisar for over 100 years and have bred to five and six generations. In the case of the Joostensz family, the known date of birth of the eldest Kisar-born child of European blood was 1789. His descendants down to the year 1914 numbered 38 at least and possibly more. His father, J. W. Joostensz, commandant at Kisar in 1817, was born at Macassar in 1767, giving an uninterrupted period of tropical residence for this family of 154 years on the paternal side and at least 135 years on the maternal side.

2. That this has not been accompanied by loss of European characteristics of complexion and features, except as a result of admixture of native blood, and that even when so diluted the European physical characteristics still come out strongly in the fifth and sixth generations.

3. That the European standard of mentality, as shown by reaction to European methods of education, persists in substantial degree after five and six generations.

4. That these characteristics have survived in spite of environmental conditions and associations lasting for over 60 years, from 1819 onwards, and probably for some 70 years or more, which are generally supposed to be totally unsuitable for persons of European stock. These conditions have included native standards of food and food-supply, endemic malaria, the psychological effect of what must have been for the earlier generations an acute sense of abandonment by their own race, life under the rule of native chiefs, constant association with a native race of low mentality, loss of European language and European religion, interbreeding to a high degree, and constant exposure to a tropical climate.

5. That there is nothing in the available history of these people to show that a tropical climate *per se* has tended to produce degenerative effects on them or to limit fertility.

6. That whatever evidence they may have shown of lowered physical or mental activity in the past can be fully explained by the environmental conditions of food-supply, malaria, and particularly of native associations, aided possibly by the accentuation of stock-weaknesses arising from interbreeding over several generations.

7. That the measures adopted by the Government during recent years appear to have resulted in definite improvement in their physical and mental condition, particularly amongst the children of school age.

This is a remarkable record, but the very admixture of native blood may have played a part in the development of resistance to climatic conditions. It would appear that there are disturbing factors and there is an admission of distinct lowering of the physical and mental standard in the past, which, in its turn, may have been due to the mixed blood. The supposed ill-effects of inbreeding are, as ever, suggested, but apart from what Ruffer has shown regarding the Ptolemies, observations made in France and Denmark on the vitality of children resulting from the marriages of

first cousins do not appear to prove that such unions are deleterious.

It may be said that although these various instances prove, or seem to show, that a white race can persist in the tropics without degeneration, mere persistence is no great matter; and it may be asked have any of these communities produced individuals of note, persons of outstanding ability, such as they would almost certainly have evolved had they existed in temperate climes? In this respect history is silent, but it must not be forgotten that a great deal depends upon opportunity and that these isolated islands afford little scope to those, if any such there be, with the capacity of rising above their fellows. It is, I think, curious that most of the examples cited concern the Dutch, and it may be thought that the stolid and persevering Dutchman is better adapted to withstand the malign influences of the tropics than other north European races of a more sanguine temperament, but, as we shall see later, this would not appear to be the case. Moreover, there are said to be signs of degeneracy amongst the members of the third generation of a Dutch colony founded in 1845 on the Saramacca River in Dutch Guiana.

CUBA.

One cannot overlook a paper published by Dr. Juan Guiteras in 1913. He also deals with an island which I have been privileged to visit, but it is a very large island, the Pearl of the Antilles. The race of which he writes is Spanish, not Dutch, and he is very emphatic in what he says, and answers some of the questions I have raised. Being the Director of Health and a Cuban by birth, he speaks with authority, and as the result of ripe experience. Briefly reviewing the history of the subject, he recalls various disasters which have attended white settlements in the tropics, and asks if malaria and hookworm were not the destructive factors rather than the climate itself. He notes the tendency there has been to ignore the accomplishments of the Spaniards and Portuguese in the colonisation of the tropical regions of America, and believes this has, in large measure, been due to a misunderstanding as regards the word "creole," which in Cuba does not signify a half-breed. The general death-rate for the island is low, even though there are no altitudes sufficiently lofty to bring about conditions like those of a temperate or even a sub-tropical zone. The coloured population compared with the whites is said to be slowly diminishing, and evidence is advanced to show that the white race has not only persisted, but prospered without any intermarriage with black or coloured folk, and without the frequent introduction of fresh elements from the temperate zone.

The highest proportion of whites is found in the Province of Camagüey, where there are extensive plains favourable for stock raising. Hence, sugar-cane and coffee plantations with their, as Guiteras terms it, *necessary* accompaniments of negro slave-labour, do not enter into the industrial life of the province. Until recently it was difficult of access, so that there was little immigration. Says Guiteras:—

"Now the interesting fact in connexion therewith is that this province, with a minimum of intermixture of the white and black races, and with a minimum of importation of a new white element from abroad, presents the finest type of the white race in Cuba; the people of this province are rather tall, handsome, often fair-eyed, with fine sunburned complexions and dark hair. Though the number of the population is below that of the other provinces, Camagüey has contributed its quota of men of action and high intellectual attainments. There we find also the largest families on the island. The average size of the family in Camagüey is 5.5. For the native white family it is 5.8, and for the white foreign and the negro families it is 5.0. In the rest of the island it is lower. The minimum is reached in Matanzas, with 4.2. In many of the families of Camagüey the Spanish ancestor has to be sought several generations back. In the province of Camagüey the mortality is low and the birth-rate high, 38.6 for the year 1912. The death-rate in 1912 was 11.15. The province of Pinar del Rio is the only one presenting a lower figure, 10.25, but its birth-rate is low, 22.8 for the year 1912. The Province of Camagüey also presents the highest death-rate from old age."

The white Cuban family is also found everywhere throughout the island and, in the country districts, consists of a hardy race of medium stature, dark-complexioned, lean, frugal, and industrious. Guiteras thinks the Spaniard has taken kindly to acclimatisation owing to his method of living, which we will consider later, and his sobriety as compared with northern Europeans. He sees no lack of energy either amongst adults or children. The peasants work the fields the whole year, the child is vigorous at games, the Cuban generally active, lively, and talkative. It is worthy of note that Cuba, with a population a little over 2,000,000 inhabitants, exports products of her soil and her industries at the rate of over \$110,000,000 a year. Finally, although Guiteras admits that the proper channels of energy are generally lacking or misdirected at the present time amongst white communities of the tropics, he has no doubt that a reservoir of Caucasian energy is to be found there, and to prove his point, cites Alexander Hamilton, born on the island of Nevis and accounted by some as the possessor of the finest intellect ever bestowed on man, and Carlos Finlay, a notable pioneer in tropical medicine.

Certainly in the hands of Guiteras the white race in Cuba makes a good showing. Perhaps the Spaniard is on rather a different footing from the more northern European. His home country is a land of the sun, at least for a goodly part of each year. Many a Spaniard has a touch of Moorish blood coming originally from subtropical lands, and his very swarthinness may aid him. Again, modern Cuba undoubtedly owes much to the restless and pushing American, who in some parts may possibly have supplied the stimulus which the climate may not furnish. These, however, are but conjectures, and Guiteras's contribution to the discussion must be given due weight and cannot be lightly set aside. Certainly it contrasts with Hintze's statement to the effect that the Spanish and Portuguese settlers have become so mingled with the indigenous population that in the whole of Spanish and Portuguese America (which presumably includes Cuba) scarcely a single pure-blooded white family can be found. I am, however, inclined to think that this is too sweeping an assertion. Such families certainly do exist at Bogota in Colombia and in other parts of South America.

THE BAHAMAS.

Huntington, who is not of the school of Guiteras. Stokris, Manson, Sambon, and, it may be added, Gorgas, has something very different to say, and, like Hintze, he goes for his proofs in part to island communities. What he writes about the Bahamas is highly suggestive. Now the Bahamas lie outside the tropic belt, but anyone who has been at Nassau must admit that there is something very tropical about its bright, strong sun, and the vivid blue of its sea. In any case, the fact that the Bahamas are only sub-tropical adds weight to Huntington's findings. The islands are healthy. Malaria is uncommon and ankylostomiasis is said to be practically unknown, probably owing to the fact that even after the heaviest rain the soil dries with remarkable activity, and is therefore unfavourable for the development of the hookworm larvæ. The white colonists came partly from Great Britain, partly from Georgia and other Southern States, which, being Loyalists, they left at the time of the War of Independence, sacrificing all to live under the shadow of the Union Jack. This alone shows that they must have been people of some character and independence. Indeed, they were of the same stock as those who emigrated to Canada. The latter prospered, but the former have retrogressed. It is true that a certain moiety of the better class Bahamans have, as Huntington puts it, retained their inheritance, and that the younger members of the community have frequently, in the northern United States or England, shown marked ability, but a large proportion have become "poor whites"; the stigma is upon them. They are described as having an intense and bigoted speech, sunken cheeks and eyes, sallow complexions, and an inert way of working. They, like the negroes about them, till the soil, sail boats, and

gather sponges, but in some respects they have fallen below the level of the negro. They are his inferior in strength, docility, and faithfulness, though they beat him in mental quickness and initiative, relics of a priceless inheritance; and Huntington considers various causes which may be to blame—monotony in diet, an easy life due to a fertile soil—though, as a matter of fact, hard tillage is required, for the soil if rich is thin and the abundant rocks preclude the plough. Hurricanes, isolation, and so forth, are all mentioned, but the author concludes that the root of the matter is the inertia due to climate. It is, to put it tersely, a slack climate. The quaint remark of an American is recorded: "Until I came to the Bahamas," said he, "I never appreciated posts. Now I want to lean against every one that I see."

The thermometer in the Bahamas practically never goes below 50° F. There is a lack of stimulus both to the body and to the mind. The same, according to Steudel, is true of Samoa, where the pure German race did not flourish and the situation was saved by the development of half-breeds.

MAURITIUS.

Mauritius, an island just within the tropics but the happy possessor of a climate so modified by its southerly situation, the surrounding ocean, and the influence of the trade winds that it cannot be termed tropical save in the coastal zone during the summer months, is worthy of passing notice. As in the Bahamas, climatic conditions are mild and equable, and there can be no doubt that Mauritius is in many ways a lotus land. Yet none can declare that the European community, consisting largely of the descendants of French families and numbering some 10,000 souls, are lacking in intelligence, energy, or enterprise. Indeed, considering its size and remoteness, Mauritius has produced a remarkable number of distinguished men, amongst whom one may merely mention Brown-Séquard, the famous physiologist, and Prosper d'Epinay, the distinguished sculptor. Even before malaria drove the white colonists out of the coast towns, and forced them to live anywhere up to an altitude of 1800 ft., there was no sign of decadence. It is what we may call an easy-going and pleasure-loving spot, but physically and mentally its white people, a considerable proportion of whom possess some tincture of Indian or Creole blood, can hold their own with most races. At any rate, there is nothing comparable to the "poor white" Bahaman, and yet the temperature never and nowhere falls below 44.6° F. Is it, then, because of race, altitude, soil, or general social conditions that the "poor white" Mauritian scarcely exists? I confess the question is puzzling, but it is probably an economic one, for few of the Europeans in Mauritius have ever been hewers of wood or drawers of water.

After all, however, islands, at least of the type with which so far we have exclusively dealt, have certain peculiarities. The sea and the sea breezes modify their climates, they are isolated, life upon them is circumscribed, they are centres of monotony. Hence it is well to cull examples from other sections of the globe. Changing the order in which we have considered the protagonists of the two opposing theories and taking Huntington first, we find that he scarcely considers any of the extensive land stretches in the tropics from the point of view of white settlement, though he has plenty to say about their native inhabitants. Curiously enough, he ignores tropical Australia, possibly because its colonisation is so recent, possibly because its European population is small. Into the interesting comparison he draws between the inhabitants of the southern and northern United States we need not enter beyond mentioning that he finds for the Yankees, gives good reasons for so doing, and states them in a very courteous and pleasant manner.

SOUTH AFRICA.

What he says about South Africa is perhaps more to the point, for some of the Transvaal and the whole of Rhodesia lie within the tropic belt. He is, I confess, rather surprising on the subject. Although I know

something of South Africa I admit that I had no idea that a large number of the Europeans—even a tenth, according to ardent believers in the future of South Africa—are "poor whites," a shiftless set, living from hand to mouth, proud of their race, yet less efficient than the blacks. Accordingly I referred the matter to Colonel P. G. Stock, of the Ministry of Health, who knows South Africa intimately, and he confirmed Huntington's statement, pointing out, however, that in parts of the Transvaal chronic malaria may be to blame. "Most of them," says our author, "appear to have been born in the country and lack initiative and energy." He goes on to remark that the problem is economic, but that, as he puts it, "back of the economic facts, and in many ways conditioning them, lies the climate." What follows will be news to some. "South Africa," he continues, "is supposed to have a climate admirably adapted to Europeans. I shared the common opinion until I began to gather statistics of the effect of climate upon efficiency. These, as will be shown later, indicate that although the South African climate is pleasant, it lacks the stimulating qualities which are so important in Europe and North America. The lack of stimulus increases rapidly as one goes from south to north."

In the civilisation maps which form such a feature of his book, while England and the Northern United States stand at 100, the Union of South Africa has only 72 to its credit, a somewhat low figure even when the presence of a large native and coloured population is taken into account. Huntington maintains that the white settlers are everywhere at a disadvantage compared with the natives, especially the Bantus, who by coming south have bettered their climate. He says that no one can predict what will happen, but it is scarcely conceivable that he entertains doubts as to the future of the white South African nation. In any case, the consideration has rather led us away from the tropics, though its interest may perhaps atone for the digression.

CLIMATE AND THE NERVOUS SYSTEM.

Huntington, then, though he proceeds on lines of his own in magnifying the importance of climate *per se*, belongs to the school which subscribe to the dicta of Anderson, another American. I need only mention four of these, which are to the effect that in the tropics the white man, individually, can exist, racially he cannot persist; that acclimatisation is not possible; that only by partial enslavement of the coloured natives, superior in numbers, can the white man rule and govern in the tropics, and it is only by relays of fresh representatives he can continue his sovereignty; that no colony of northern origin has even been able to lead a permanent and independent existence in the tropics. Sir Havelock Charles is a stout supporter of this view, starting from Cuvier's axiom that "The nervous system is at bottom the whole animal, and the other systems are only to serve it." He maintains, therefore, that if you damage the subservient systems you harm the whole animal—i.e., the nervous system—and that tropical climates injure the various systems of the body apart altogether from the dangers of attack from parasitic enemies.

This, it may be said, is quite at variance with the opinion expressed by the Tropical Diseases Board and by Chamberlain in the Philippines, to return for a moment to islands of the sea. They found that there was no evidence of any serious effect on the nervous system of American soldiers as the result of the Philippine climate, but after all they were only dealing with the short period of five years. And yet perhaps the broad verdict of history to which Anderson and Sir Havelock Charles appeal carries more weight than countless arguments. A few swallows do not make a summer, and isolated examples like those quoted from the West Indies, Kisar, and so forth must be weighed against the silent testimony of the centuries, even if it is admitted that only of late years has it been possible to combat those disease concomitants of climate to which some would attribute wholly the malign influence of the tropics.

PANAMA.

Let us, however, see what further proofs these advocates can advance. Gorgas speaks with no uncertain voice:—

"The real scope of tropical sanitation, which has been almost entirely developed within the last 15 or 20 years, I believe, will extend far beyond our work at Panama. Everywhere in the tropics, to which the United States has gone in the past 15 years, it has been shown that the white man can live and exist in good health. This has occurred in the Philippines, in Cuba, and in Panama, but the demonstration has been most prominent and spectacular at Panama, and therefore has attracted there the greatest world-wide attention. Here among our large force of labourers we had for ten years some 10,000 Americans—men, women, and children. Most of these American men did hard manual labour, exposed to the sun, rain, and weather conditions day in and day out, yet during that time their health remained perfectly good, just as good as if they were working at home. The same remark as to health would apply to the 4000 women and children who lived at Panama with their husbands and fathers. Both the women and children remained in as good condition as they would have been had they lived in the United States. This condition at Panama, I think, will be generally received as a demonstration that the white man can live and thrive in the tropics. The amount of wealth which can be produced in the tropics for a given amount of labour is so much larger than that which can be produced in the temperate zone by the same amount of labour that the attraction for the white man to emigrate to the tropics will be very great, when it is appreciated that he can be made safe as to his health conditions at a small expense. When the great valleys of the Amazon and of the Congo are occupied by a white population more food will be produced in these regions than is now produced in all the rest of the inhabited world."

Here, indeed, is a hopeful prophecy, but let it not be forgotten that though Gorgas was a splendid man and a great practical hygienist with fine driving power, he is not generally regarded as in the first rank of scientific observers. He may be right, but I saw some of these same Americans in Panama and they struck me, more especially the women, as spiritless and tired. Doubtless there were exceptions, but the people I met were those who were keeping the flag flying after all the strenuous work had been done, the great undertaking completed. They were no longer buoyed up by expectation and by the thrill of great events, and to my mind they were beginning to suffer—not from disease, but from the effects of climate. I greatly doubt if we shall ever see succeeding generations of Panama-born Americans.

ESPIRITO SANTO, BRAZIL.

But Gorgas does not stand alone. Wagemann has described the German colony of Espirito Santo, Brazil, which is on the coast, at 20° S. It was founded in 1847 and the original Rhenish families have been reinforced on several occasions. The pioneers were nearly conquered by nature and disease, but eventually made good. Now 5000 square kilometres have been settled and there are eight communities, comprising in all 17,000–18,000 souls. The colony is flourishing. The birth-rate in various parts is between 48 and 70 per 1000 and the death-rate 8–14 per 1000. There has been no intermarriage with the natives. One would like to know more about this interesting experiment, but we can only note that it has not been very long in existence and hesitate to draw any definite conclusions from it.

RHODESIA.

On our way across seas to Australia, where a battle-royal has been waged and is still in progress over this question, let us glance for a moment at Rhodesia, especially in view of Huntington's remarks on South Africa generally. There we find an advocate for white settlement in the person of Dr. A. M. Fleming, who has been the principal medical officer of Southern Rhodesia for many years. He admits that Rhodesia is a new country and that the European adult population are not yet acclimatised to the land of their adoption, but, provided disease is kept in check, he sees no reason why they should not flourish there. He recalls the early days when almost everyone in the country looked

yellow, anæmic, and fever-stricken at certain seasons of the year, when it was openly said that Southern Rhodesia was no country for a white man and when he himself had misgivings on this score. Now he states that at any gathering of settlers at Bulawayo, Salisbury, or other centre it would be hard to find a collection of people whose general physical fitness was so apparent or who exhibited less evidence of degeneration. He lays special stress on the satisfactory development of the children both mentally and physically which he considers rather in advance of that seen in children of the same social status in more temperate climates. Hintze, though cautious, seems inclined to agree with him, but recently Hewetson took up the cudgels on behalf of the opposition. He points out that miscarriage is more common in white women in the tropics than amongst the blacks, and that the general birth-rate is lower. (There are, however, surely other reasons than climate to account for these differences.) On the other hand, like Sir Havelock Charles, he concentrates on the question of neurasthenia and the malign effects of constant sun and excessive heat. The more one studies the literature, which has now attained formidable dimensions, the more is one reminded of a game of nine-pins. No sooner are arguments advanced by one protagonist than they are demolished by another, and there are doughty champions on either side.

AUSTRALIA.

It is impossible, in the time at my disposal, to discuss all that has been written on the subject of a white Australia. Only a few salient points can be considered. Tropical Australia contains no less than 1,149,320 square miles, and the development of this huge area depends on whether white men can live and work in it, not as they live and work in a country like India, but as tillers of the soil, as herdsmen, as labourers pursuing all those avocations which, as a rule, fall to the lot of the coloured races in the hot regions of the globe. The problem, as Breinl and Young pointed out, is by no means simple, for it includes not only the effects of climate but important economic considerations. Sir James Barrett has laid stress on the latter, but to-day we are only concerned with the former, and in considering them we must remember that the conditions in Northern Australia are somewhat specialised. Breinl and Young comment especially upon the hot winds, the frequent droughts, the influence of the long dry season on insect life and on tropical diseases which are insect-borne, and contrast the conditions of the littoral with the hinterland.

Although it is true that the desert regions of northern Australia differ from what many have in their minds when they think of the tropics, yet they possess their counterpart in countries like the Northern Sudan and Mesopotamia, where no question of white settlement has ever been mooted, or is likely to be. On the other hand, the scarcity of the aboriginal inhabitants is a distinctive feature and possesses considerable importance. It was doubtless partly as the result of experimental work carried out by Breinl, Young, and Priestley at Townsville in Queensland, and in view of the vital statistics which they collected, that the Subcommittee of Investigation, appointed by the Australian Medical Congress held at Brisbane in 1920, issued the following pronouncement:—

"After mature consideration of sources of information embodying the results of long and varied professional experience and observation in the Australian tropics, the Congress is unable to find anything pointing to the existence of inherent or insuperable obstacles in the way of permanent occupation of Tropical Australia by a healthy indigenous white race. It considers that the whole question of successful development and settlement of Tropical Australia by white races is fundamentally a question of applied public health in the modern sense, such as has been demonstrated and practised with success amongst civil populations under far more difficult conditions, by the American authorities in the Philippines prior to the Great War, and throughout the military forces of every allied power during that war. It considers that the absence of semi-civilised coloured peoples in Northern Australia simplifies the problem very greatly.

But it desires to emphasise in the strongest manner that any considerable extension of population and settlement under the existing loose conditions of sanitary administration and sanitary practice, using these terms in their modern wider sense, which prevail at the present time in Tropical Australia, cannot hope for lasting success, and cannot fail to result in ultimate disaster. The Congress recognises that a large amount of work still requires to be done in working out the practical details of any scheme of settlement, but it considers that it presents no difficulties beyond those of organisation, staff, time, and money. It realises that a great national question is involved, but it is unable to discern any obstacles which cannot be overcome by earnest and skilful application of the principles of statecraft."

A large majority of the Congress adopted this resolution, but there were not wanting dissentient voices. For example, Nisbet, of Townsville, speaking from 31 years' experience, affirmed that the population of North Queensland was migratory, the death-rate low because it was the desire of inhabitants to get away from it during the autumn of their lives. The report of the Subcommittee dealt chiefly with the male population, but the young married women, according to Nisbet, were greatly overdone with domestic duties under conditions of great heat and humidity—the said heat leading to debility and neurasthenia. He was of opinion that the evil result of the northern climate would not be obvious till they had a settled population.

Since 1921 a few papers have appeared which merit attention. Sir James Barrett gives general mortality and infant mortality rates for the whole of Queensland from 1911 to 1920 inclusive. In 1920 the general mortality rate was 11, the infantile mortality rate 63. For each of the years specified the general mortality rate for Queensland was below the Commonwealth average on six occasions and above it on the other four. In respect of infant mortality, Queensland was below the Commonwealth on nine occasions and above it on one only. Sir James, however, does not take Nisbet's statement into account, nor does he consider that the Commonwealth statistics are concerned much more largely with urban conditions than those of Queensland. It would seem also that there has been a tendency to regard Tropical Australia as synonymous with Tropical Queensland, which is unfortunate, for Tucker has drawn attention to the fact that nearly two-thirds of Queensland consist of a region about 100 miles from the sea, averaging 800 ft. in height, and possessing a fine winter climate and a tolerable summer climate, with—and this is very important—cool nights. There is a wide variation between the wet and dry bulb temperature, and hence a rapid evaporation. Tucker, indeed, furnishes much the same information as Prof. Skertchly, the geologist, to whose writings Sir James Cantlie recently drew attention. Priestley has recently stated that he found no signs of deterioration in the third generation of children born in the Australian tropics, an important pronouncement. Unfortunately, full particulars have not been forthcoming.

The latest, and one of the best contributions to the subject, is a paper by Cheyne which will be found in the *Journal of Tropical Medicine and Hygiene* for March 1st of this year. It should be studied in the original by all interested in the problem, for not only does he give a useful physiographical and meteorological account of the whole area of Tropical Australia, so far as it is known, but he discusses the question of the rôle of the sun, the prevalent diseases, various economic factors, health conditions, and very specially the effect of the climate upon the women. He agrees with Nisbet that they find the conditions trying and are frequently neurasthenic, but says that whether the climate or the environment is to blame is a moot point.

The following are his conclusions:—

"With our present knowledge there would appear no scientific reasons why white people should not successfully inhabit the north. These conclusions, however, must be accepted with caution, and will have to bear the test of time. Three or four generations of whites, born, bred, and intermarried in the tropics, must elapse before the problem can

be considered as solved. Meanwhile, every effort should be made to carry out under good conditions this vast physiological experiment. Under present circumstances, whether the north will become closely settled by whites is quite another matter. The north, taken as a whole, appears more suitable for sheep and cattle grazing than for close settlement. Griffith Taylor, after a careful comparison of meteorological conditions, says that the northern lands are not well suited for close white settlement. This is chiefly because of the lack of surface water, and of the monsoonal character of the rains, which cause a prolonged dry spell during the winter. There are, however, several rivers in the Gulf country, such as the Roper, which flow throughout the year. No doubt, under present conditions, Taylor's conclusions are just, but with our knowledge of what modern irrigation has done, there is no reason why—apart from economic questions—large areas should not be made available for fruit and cotton growing. Some observers seem to imagine that coloured races can be permitted to enter the north and remain confined there. This is contrary to common-sense, and the ultimate and logical termination to the admittance of coloured races would be the eventual formation of a mixed Australian people. Any sacrifice is worth making which keeps Australia white."

With Cheyne's conclusions I may fittingly conclude this lecture.

MANCHESTER HOME FOR INEBRIATES. — The Manchester Watch Committee have agreed to hand over their interest in the Inebriates Institution at Langho to a subcommittee of the Lancashire Asylums Board for the treatment of mental deficients. Since 1915 it has been used to a greater or less extent for this purpose. The institution was built over 20 years ago at a cost of £110,000 and was designed for the reception of inebriates, male and female, but only that portion of it which was intended for women was erected. Women had to be committed by magistrates three times in a year before they could be sent to the home, and only then by their own consent. The third committal was rarely reached, and for some time not a single inebriate has been under treatment there. It would seem that the majority of the patients at the time of their committal to the institution had already passed the period at which reformatory treatment would be of any use. The chairman of the Watch Committee said that the treatment of inebriates at such places appeared unfortunately to be ineffective. On many occasions women leaving Langho have gone and bought themselves a drink. It has proved a failure in public administration.

RESEARCH IN TROPICAL DISEASE.

PUBLIC announcement was made last week that there is in process of organisation the nucleus of an institute, to be called the "Ronald Ross Clinique for Tropical Diseases and Hygiene," as a fitting monument to a great investigator on the twenty-fifth anniversary of his discovery—a discovery which revolutionised medical science and living conditions throughout the tropics. The distinguished signatories to the appeal for this Ross Institute expressly state that the proposal is to supplement and in no way to compete with existing schools of tropical medicine. No doubt instruction in this fruitful and rapidly expanding branch of medicine must necessarily go hand in hand with research—one cannot exist or flourish without the other, and we take this opportunity of indicating some of the directions in which the special schools have proved their value, leaving aside for the moment the work of such foundations as the Lister Institute, the National Institute for Medical Research and others, which take in the tropics in their stride.

I. LONDON SCHOOL OF TROPICAL MEDICINE.

The London School of Tropical Medicine has been in existence for 24 years and starting from small beginnings it has expanded until in 1920 it was transferred from its former and somewhat obscure position in the Albert Dock and installed in Endsleigh-gardens in close association with the Hospital for Tropical Diseases and the Tropical Diseases Bureau. Since the removal three years ago the 56 beds have been filled with examples of interesting and rare diseases from all parts of the British Empire. In association with the hospital itself, a laboratory has been specially fitted up for clinical investigations and clinical research, and the activities of the helminthological, protozoological, and pathological departments of the School testify to the value of the coöperation between the wards, the research laboratories, the lecture theatres, and the bureau from which is issued the *Tropical Diseases Bulletin*.

Among the results of practical importance derived from the association may be mentioned a new theory and treatment of sprue by Dr. H. H. Scott, now a member of the School and himself a former sufferer from this terrible scourge, as also the discovery of Weil's disease in London and the treatment of trypanosomiasis by Bayer "205." The staff of the hospital counts among its numbers a distinguished physician who has been appointed in order to originate and conduct research in clinical medicine. Certain tropical diseases, sprue among them, are probably more profitably investigated in London than in the tropics. It has, however, been fully recognised that the really great advances are to be obtained by special researches in the tropics themselves. This can be done in two ways: by training workers for positions in the laboratories now established in most of the British tropical possessions or by the despatch, from time to time, of special investigators most fitted to conduct an intensive research for a limited length of time on some special problem.

During the last 23 years the School has despatched no less than 21 of these expeditions and, as the publications of the School will show, they have been fruitful in many ways. The researches of C. M. Wenyon in protozoology and R. T. Leiper in helminthic disease are known to all. At the present moment two of the staff are actively engaged in research in the tropics. Dr. J. G. Thomson, for the second time, is investigating blackwater fever in Rhodesia, and Dr. H. B. Newham the prevalence of undiagnosed fevers in British Honduras, while at the end of the present year Dr. P. A. Buxton, accompanied by assistants, is proceeding to Samoa with the coöperation of the New Zealand Government, with the object especially of devising methods for the prevention of filariasis. Dr. Cecil Cook, the recently appointed Wandsworth scholar, will investigate the aetiology of ulcerating granuloma in New Guinea, where this intractable and loathsome disease is rampant.

This active prosecution of research in the tropics has been made possible owing to the endowment by Lord Milner of a magnificent research fund with an income of over £2600 a year. The helminthological department also expends over £1000 a year in special research facilities, and Prof. Leiper has constantly attached to him three or more research students, their activity being reflected in the publication of the bi-monthly periodical the *Journal of Helminthology*. The publications of the School as a whole include the production of the *Journal of the London School of Tropical Medicine* as well as the *Research Memoir* series, of which four volumes have already appeared and others are in course of preparation.

The London School thus provides ample and generous opportunities for laboratory and clinical research, the popularity of which is reflected in the increasing attendance at the post-graduate classes. Still greater opportunities are assured to the School in association with the scheme for an Imperial Institute of Hygiene.

II. LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

The Liverpool School of Tropical Medicine was founded in 1898 by the late Sir Alfred Lewis Jones. The early history of the school is a record of struggle; it was not supported by the Government, as was the London School; it had no grant, no assured income, nor even, until 1900, Government recognition. The teaching staff, of which Ronald Ross was an original member (becoming, in 1903, the first holder of the Alfred Jones Chair of Tropical Medicine), was originally appointed in May, 1899, and it was actually in July of the same year that the first scientific expedition sailed for West Africa. A series of expeditions followed rapidly, and up to the year 1914 the school has despatched 32 expeditions to the tropics. In addition, the services of members of the staff have been requisitioned from time to time for special investigations in the tropics, and as recently as 1921 a member of the staff proceeded to Venezuela to investigate an outbreak of malaria.

The year 1922 marked a new phase in the scientific activity of the school, for in January of that year its research laboratory at Freetown, Sierra Leone, was opened with a director (holding a professorship in the University of Liverpool) and two assistants as a preliminary staff. Thus was realised a long-cherished desire of investigating the diseases of a given locality at their place of origin, the extension of this scheme being limited only by the means at disposal.

As to the scientific work of the school done in its laboratories in Liverpool, the *Annals of Tropical Medicine and Parasitology*, first published by the school in 1907, and now in their seventeenth volume, are maintained largely by contributions from the staff. Notable among many advances in tropical medicine promoted by the staff of this school are the researches into blackwater fever by Wakelin Barratt and Warrington Yorke, into yellow fever by Wolferstan Thomas and Rubert Boyce, and into trypanosomiasis by J. E. Dutton, J. L. Todd, and C. Christy. From Prof. B. Blacklock, working at the recently established laboratory in Sierra Leone, has already emerged the discovery of a malarial parasite in the chimpanzee, identical in morphology with the human parasite *P. falciparum*, and some evidence that blackwater fever is not due to a specific parasite. The school has investigated and is at the present time investigating several of the scientific problems that have arisen in the city and port of Liverpool—i.e., the house-fly pest, the existence of plague-fleas on ship rats, the presence of mosquitoes in incoming vessels, the destruction of bed-bugs and rats on ships. The speciological work by members of the staff, on its collection of parasites from all over the world, is another aspect of the school's activity.

Further details, indicating the nature of the work and the wide field which it has encompassed, are set out in the *Historical Record* and the *Scientific Record* of the school, published in 1920 at the University Press, Liverpool.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The New Medico-Legal Institute of the University of Paris.

A NEW Medico-Legal Institute has recently been inaugurated in Paris, the Department of the Seine and the University of Paris having voted considerable sums towards its erection. The Institute will replace the old Morgue which stood at the Quai de l'Archevêché till this year, and has long been the object of morbid curiosity. The Morgue consisted of a gallery to which the public were allowed access, where dead bodies were exposed for identification purposes. Since 1913 this public exhibition of bodies has been suppressed, but the building which remained had a gloomy aspect and spoilt one of the prettiest corners of Paris. It has now been demolished, and will be replaced by a garden which will pass along the banks of the Seine behind the apse of Notre-Dame Cathedral. The new Medico-Legal Institute is built near the Pont d'Austerlitz. The ground floor consists of a large gallery giving access to an amphitheatre big enough to seat 200, fitted with modern equipment, including arrangements for showing films and technical apparatus. The laboratory of forensic medicine is also well equipped, arrangements for work in vacuo and for the production of compressed air being provided. The rest of the ground floor is taken up by the private laboratory of the professor, the museum, library, and a large teaching laboratory, along the bank of the Seine, where many students can be accommodated. In the basement are photographic dark-rooms and rooms for experimental animals. On the side of the building connected with the University of Paris are well-arranged administrative departments, a record office, and a hall for identification of corpses placed just under the galleries of the basement. Here cadavers are to be kept in separate cases at a low temperature. Special accommodation has been reserved for the officials concerned with identification, for photographing the cadavers. This well-equipped Institute does credit to the University of Paris and to the Department of the Seine.

Medical Examination of Motor-drivers.

In view of the number of motor accidents, the Commission d'Hygiène of the Chamber has just decided on the necessity for imposing a medical examination on all candidates for a licence as motor-car drivers. This measure is approved by the Association Générale Automobile de France, and the Academy of Medicine is also strongly in favour of its provisions. No chauffeur will be excused from examination, whether he be the driver of a taxi, private car, lorry, or omnibus, whether he be an owner-driver or an employee. The proposal is to require a medical certificate attesting that the candidate has good general health, normal vision, or, if the vision is abnormal (myopic or hypermetropic), the visual acuity after correction by glasses must be 8/10. Moreover, the commission consider that it will be necessary to refuse a driver's licence to all alcoholics, because, whether they are actually suffering from the effects of a drinking bout or not, intemperate habits in the long run will render them incapable of retaining that self-control, presence of mind, and precision in manipulation which are indispensable in a good chauffeur.

Diminution of the French Birth-rate.

Detailed statistics of French population during 1922 have recently been officially published. If the records of the last three years are compared it will be found that while the excess of births over deaths amounted to 159,790 in 1920 and 117,023 in 1921, the margin is reduced to 70,579 in 1922. Marriages per 10,000 inhabitants were 195 in 1922, compared with 233 in 1921 and 318 in 1920. The birth-rate per 10,000 inhabitants was 194 in 1922, against 207

in 1921 and 213 in 1920. The mortality per 10,000 was 176 in 1922, against 177 in 1921, and 172 in 1920. In short, there was in 1922 a diminution of marriages and of births which is not compensated for by the very slight reduction in mortality rate.

June 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons in Ireland: Dinner to Dr. William Mayo.

ON June 25th a dinner was held at the Royal College of Surgeons in Ireland in honour of the visit to Dublin of Dr. William Mayo, of Rochester, Minn. Upon the same occasion the Honorary Fellowship of the College was conferred upon Sir Harold Stiles, Regius Professor of Clinical Surgery, Edinburgh University. Sir William Wheeler, President of the Royal College, presided. The parchment signifying that Sir Harold Stiles's name had been placed on the roll of honorary Fellows was handed to him by Mr. T. M. Healy, Governor-General of the Irish Free State.

In proposing the toast of the Governor-General and prosperity to Ireland, the President referred to the College as an institution which knew nothing of politics or sectarian strife. This impartiality, he said, had been reciprocated in the course of the past few years; the College buildings had been occupied or besieged at different times by three separate military forces hostile to one another. Many of those present, he continued, had had, in the capacity of medical witnesses, experience of the deadly accuracy of Mr. Healy's methods in the course of his legal work. He was now engaged in the work of a physician and surgeon, reconciling difficulties, and healing and preventing contention.

Later, in giving the toast of the honorary Fellows, coupled with the names of Dr. William Mayo and Sir Harold Stiles, Sir William Wheeler referred to the latter as honoured guests who, through their writings and through the tongues of patients, disciples, and followers, were daily friends of the entire community. He also referred to a visit paid by himself to Rochester; in the year previous to that visit 68,000 patients from all over the globe had sought the advice and help of Dr. Mayo and his 200 assistants. After emphasising the regard felt by the College towards Sir Harold Stiles and the wide interest in his work which was apparent throughout Europe and America, the President spoke of the general practitioner and his position in the medical world as follows: "I allude to the subject, first, because it is near to the hearts of both Dr. Mayo and Sir Harold Stiles, and secondly, because I want to tell them before they leave us that the general practitioner in Ireland has lived up to the high reputation which they have given to him. The general practitioners in this country have carried out their duties under conditions which would almost make those trained in the profession of arms shrink and retreat. It was no light matter to travel over roads strewn with mines and explosives at the dead of night. It was not a joy-ride to go through ambushes and trenches, of necessity by forbidden routes, to be mistaken for combatants and fired upon by friends and foes. Some fell wounded, some were killed, others escaped with their cars blown up and destroyed; but there was never an instance of refusal to attend a patient, especially a poor patient, under any circumstances whatever when the summons was received. The general practitioner in Ireland will hold an honoured place when the dreadful times through which this country has passed have been chronicled by the future historian."

The President concluded his remarks with a reference to the respect felt in Ireland for American surgeons—of whom, he said, many of the greatest bore Irish names—and to the close union between the American surgeons and the surgeons of Britain and Ireland during the war. Dr. Mayo and Sir H. Stiles briefly responded.

Irish Medical Committee.

A meeting of the Irish Medical Committee—which has not met for some years—was held on June 20th, when Dr. Joseph Power, vice-chairman, presided. Dr. R. J. Johnstone, M.P., wrote tendering his resignation of the office of chairman, but the Committee unanimously asked him to reconsider the matter. In reply to a letter from the Irish Insurance Commission inviting the Irish Medical Committee to nominate three medical practitioners to act on an Advisory Committee to the Insurance Commission (Free State), Drs. Rowlette, O'Sullivan, and Hennessy were selected. The Insurance Commission (Free State) forwarded a draft of the proposed report with regard to (1) investigation of complaints against medical certifiers; (2) the appointment of a complaints committee to investigate, in the first instance, charges made against medical certifiers, &c. After the report had been considered in detail, it was resolved:—

1. That the Irish Medical Committee is of opinion that the present arrangement whereby complaints against medical certifiers are submitted to local medical committees should be continued, and that only such cases where the local committees failed, within a reasonable time, to take action should be submitted to the proposed complaints committee.
2. That there may be allowed to either party an appeal from the decision of the local medical committee to the complaints committee.

A long discussion took place with regard to the position of the Irish Medical Services. It was resolved:

That an executive subcommittee be appointed, and that it should act as a deputation to wait on the Minister for Local Government and urge upon him (1) the necessity for the establishment of a Ministry of Health for Ireland and a National Medical Service on the lines recommended by the Irish Public Health Council; (2) pending legislation, that the deputation urge on the Minister the grievances of medical officials in regard to salaries, holidays, pensions, &c.

The Medical Secretary was directed to continue his representations to the Ministry of Local Government in connexion with the refusal of that department to sanction increases for medical officers passed by local authorities. The Committee expressed the opinion that the carrying of Red Cross badges on the motor-cars of medical men should cease with the return of normal conditions in the country. A resolution was also passed to the effect that motor-cars engaged in work under the Medical Charities Acts should be exempt from taxation, and that the tax paid on motor-cars of doctors engaged in other practice should be on the pre-war basis of allowances.

Royal Medical Benevolent Fund of Ireland.

Dr. Michael Cox, President of the Royal College of Physicians, presided at the annual meeting of the Royal Medical Benevolent Fund Society at the Royal College of Physicians, Dublin, on June 20th. The annual report states that the number of applications received during the year was 84. The amount given in grants was £1695 10s., as compared with £1215 11s. in the preceding year. Dividends and interest showed an increase of £67. Revenue from all sources, including donations, reached £3549 14s. 7d. The Central Committee states that the society is purely Irish, administered by Irish medical men for the benefit of the widows and orphans of Irish medical men who have practised in the country. The bank balance at the moment is only £888 12s. 1d., and merely to continue the work next year £1200 must be raised, or the relief must stop. The Committee appeal most earnestly to their non-subscribing colleagues throughout Ireland to consider the claims that this charity has upon them. There are over 3000 doctors in Ireland, and 10s. from each would place the society on a sound financial basis.

Queen's University of Belfast.

Dr. W. W. D. Thomson has been appointed Professor of Medicine in succession to Prof. J. A. Lindsay, who retires under the age rule. Mr. Andrew Fullerton has been appointed Professor of Surgery in succession to Prof. Thomas Sinclair, who also retires under the age rule. Mr. P. T. Crymble has been appointed lecturer in operative surgery and applied anatomy.

Correspondence.

"Audi alteram partem."

DELAY IN GIVING DIPHTHERIA ANTITOXIN.

To the Editor of THE LANCET.

SIR,—I can only infer from a perusal of Dr. H. J. Cardale's letter in your issue of June 16th that he is under the impression that in my communication of the previous week I advocated the administration of antitoxin by the general practitioner as preferable to prompt removal of the patient to hospital. I am afraid I must have expressed myself very badly if my letter conveyed that impression. Prompt removal of the case to hospital completely satisfies the requirements of the situation, since it ensures the patient getting antitoxin quickly, and ipso facto, does away with the need for the practitioner giving it. The main purport of my letter was to ensure that a patient suspected of having diphtheria should receive antitoxin early in the attack rather than be subject to the delay incidental to waiting for the bacteriologist's report. Whether the serum be administered by the practitioner at home or after prompt removal to hospital is of little moment, provided it is given early.

It is under conditions where delay in removal to hospital is likely to be encountered, such as defective ambulance arrangements, objection by the friends to the patient being sent away to hospital, or hesitancy on the part of the medical attendant to certify for removal until his diagnosis is confirmed, that I urge the desirability of his giving antitoxin. That the family doctor may have certain difficulties to contend with in giving antitoxin, as stated by Dr. Cardale, I readily admit, though some of them, I think, are overstated. Delay in procuring antitoxin certainly exists in certain areas, especially on Saturday afternoons and Sundays, owing to defective organisation. Objection raised by parents to the use of serum would hardly be expected to be more frequent than objection to their child's removal to hospital, and the arguments employed by Dr. Cardale to overcome their opposition to removal might be expected to be equally successful in overcoming their prejudice against the use of serum.

As regards the risk of anaphylaxis, I quite agree as to the need for caution in the case of persons who have been treated with antitoxin previously, and also with asthmatics, and should the history of the patient be suggestive of such being the case, it is always well to test his susceptibility to anaphylaxis by the intramuscular injection of 5 to 10 minims of serum before giving the full dose. I am convinced, however, that the risk of anaphylaxis in the case of patients who have not received antitoxin before is greatly exaggerated, and that it may be regarded as practically negligible when regard is had to the risk incidental to withholding its administration. In the course of 28 years' experience of the use of antitoxin in diphtheria, during which many thousand cases have been treated, I have only once met with a case of anaphylaxis which gave me any real anxiety, and the patient recovered in this instance.

Dr. Cardale's statement that the majority of advanced cases that are sent into hospital are in an advanced stage of the disease when the doctor first sees them, is not in accord with the experience of the medical officers of the fever hospitals, in London at any rate. Too often one hears from the friends that patients have been under treatment at home for periods of two to four days, or even more, before being sent into hospital, where they received their first dose of antitoxin. Under these circumstances I am not likely to criticise Dr. Cardale's statement "that a few doctors do delay until the diagnosis is assured is probable," except that I would substitute the words "a good many" for "a few," and "fairly certain" for "probable." To what extent the Asylums Board

were themselves to blame for this, owing to their practice of causing information to be sent to the certifying practitioner whenever the case proved not to be diphtheria, it is difficult to say, since the attitude of different doctors was found to vary a good deal in respect to the receipt of this notice. Some were glad to receive the information, others resented it, as Dr. Cardale implies. The difficulty, however, no longer exists, since the Board's Infectious Hospitals Committee decided last year, on the advice of the medical superintendents, to discontinue the practice lest it should have the effect to which Dr. Cardale draws attention.—I am, Sir, yours faithfully,

F. FOORD CAIGER.

South-Western Hospital, Stockwell, S.W.,
June 18th, 1923.

APPARATUS FOR HYDROCYANIC FUMIGATION.

To the Editor of THE LANCET.

SIR,—Your annotation with this title prompts me to write a line of warning; in doing so I have no wish to detract from the value of the apparatus as an efficient mechanism for its purpose. I would, however, urge most forcibly that there is one clear line along which to seek immunity from accidents in the fumigation of ships by prussic acid; that line is the efficient protection of the men from any concentration of gas, however great and however produced. Efficient protection resolves itself into an efficient protective apparatus, kept in perfect order, and efficient drill punctiliously carried out. A fraction of a minute's indulgence in the contempt for prussic acid gas bred of familiarity may be fatal; and it should be borne in mind that this gas, in high concentration, rapidly deadens the sense of smell, so that a man may easily be deceived as to the lethal nature of the atmosphere which he is breathing. Given efficient protection there is no danger, nor is there any reason why this method of fumigating ships with prussic acid should not be that in universal use.

I am, Sir, yours faithfully.

Cambridge, June 20th, 1923.

JOSEPH BARCROFT.

THE PROPHYLACTIC TREATMENT OF PUERPERAL SEPSIS.

To the Editor of THE LANCET.

SIR,—The precautions suggested by Lady Barrett in your last issue are impracticable in a workaday world. Some are a counsel of perfection quite unattainable in general practice, some are wrong in principle, some are founded on false assumptions. Puerperal sepsis is now rarely due to the introduction of pathogenic germs by the hands of the doctor or midwife. It is almost always secondary to some membrane being left behind in the uterus. This is often due to hastening the third stage, but not always. I make it a rule never to be in any doubt that the uterus is empty. If I am not perfectly sure, I do not hesitate to introduce the hand, surgically clean but ungloved, into the uterus. My lubricant is always soap. It has been boiled and a fresh clean surface is constantly formed during washing. It is therefore much safer than vaseline. I have never known any harm result from the introduction of the hand in this way, and have often known serious harm result from its omission. Lady Barrett greatly exaggerates the danger of manual removal. The real danger is uncertainty as to whether the uterus is empty.

The danger of oral sepsis causing puerperal infection is purely theoretical. But the danger of dental extraction during pregnancy is no "superstition," as any experienced practitioner can testify. I can recall cases of miscarriage from this cause, as indeed, who cannot? I often work with a trained midwife; our district nursing home has midwives available who work with the doctors. It is a great saving of time and removes the temptation of putting on forceps to enable the doctor to get back to his surgery.

But it is surely wrong to suggest that "an anaesthetist should be available for the whole of the second stage." Chloroform is by far the commonest cause of post-partum hæmorrhage and is often responsible for the death of the child. Many still-born deliveries are cases of chloroform poisoning. No anaesthetic should be given unless absolutely necessary, and then it should be ether, not chloroform.

It is not necessary to shave the vulva. Soap and water and perchloride solution are all that is necessary; moreover, perchloride is a far safer disinfectant than lysol or its equivalents. We cannot too persistently proclaim that parturition is a natural process and the less it is interfered with the less likely there is to be trouble. The principal function of the obstetrician should be to watch and pray! He should first make absolutely certain that there is nothing wrong, and then leave well alone. When we read the list of instruments which must be put ready it is evident that Lady Barrett expects trouble. I have forceps, a large curved needle, a needle-holder, and some silk-worm gut in my bag—and I generally leave them there.

I am, Sir, yours faithfully,

E. VIPONT BROWN, M.D. Lond.

Longsight, Manchester, June 23rd, 1923.

MODERN TECHNIQUE IN TREATMENT:

ARTICLE NO. XXV.

To the Editor of THE LANCET.

SIR,—Are these articles supposed to be practical? If so, why does the author of No. XXV. describe the technique which is only possible to be carried out in a hospital, nursing home, or good-class house? Lady Barrett appears to forget the fact that the majority of births take place in poor homes, in bedrooms in some of which I should not care to keep a dog. The mothers have never had what you may call a bath during the whole course of their existence, the bed, bedclothes, and mattress are filthy and the atmosphere of the rooms horrid. I wonder that the writer did not tell us that the bedroom should be stripped and re-papered, the bed and paint carbolised, the mattress and bedclothes stoved, the room well-ventilated and kept unoccupied until labour commences, that the mother should have a hot bath every night, and so on and so forth. Lady Barrett might also tell us the cost of a drum of sterilized dressings such as she describes, and what would be a reasonable fee for doctor and nurse to charge Mrs. Smith, who has five children, lives in two rooms, and whose husband is getting £2 a week from the "Labour."

I am, Sir, yours faithfully,

Walsall, June 24th, 1923.

JOHN G. COOKE.

THE COUNTY PATHOLOGIST

To the Editor of THE LANCET.

"We sincerely hope that any workable scheme to provide better facilities for pathological investigations in county districts will not be turned down without serious consideration."—THE LANCET, June 23rd, p. 1278.

SIR,—The last three words in your recent annotation meet the case of the county voluntary hospitals: the first difficulty to get over is to find time to seriously consider the necessity of a pathologist for the sake of the patient, and as an education for his medical attendant. Country practitioners drop into the habit of doing without—a danger to our personal work, a danger to our scientific progress, a danger of converting our great profession into a trade of pounds, shillings, and pence. A ten minutes' interview with a pathologist would often give us a different view of our patient. May I give an instance? A young man, aged 20, has a large spleen occupying two-thirds of his abdomen; a "board" calls his disease malaria; he had never served out of the country; the pathologist reports Wassermann ++ i.e. an undoubted case of congenital syphilis. A splenectomy was not done, medical treatment sufficed.

The scheme I ventured to present to representatives from the Dorset Voluntary Hospitals wanted only the determination of the profession that it must be. Two or three shillings per patient would just give the necessary honorarium, and the enormous progress in medicine and surgery requires expert confirmation of clinical observation. The greater hospitals are "out at elbow," the lesser hospitals are financially sound; both must pull the same boat if the voluntary system is to continue.

I am, Sir, yours faithfully,

W. B. COSENS.

Senior Hon. Surgeon, Dorset County Hospital.
June 25th, 1923.

DURATION OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—In his address on the Duration of Pregnancy in its Medico-legal Aspects, which appeared in THE LANCET of June 16th, Dr. T. W. Eden quoted some salient points from the case of prolonged gestation which I read before the Obstetrical Section of the Royal Society of Medicine in October, 1921. Two points were omitted by Dr. Eden: first, the patient was examined twice, on Nov. 20th and on Dec. 18th, 1917—that is, 27 and 31 weeks after the husband's visit, and the uterine size each time corresponded with the pregnancy history. If the pregnancy began early in July, these dates would correspond to 20 and 24 weeks. Foetal movements were noticed in December at the second examination. On March 19th the uterus had reached its full size. The second point refers to war-time morality: the husband had been away for four years, three of them war years, and, further, the last pregnancy was 18 years ago. I do not think that prolonged gestation can be negatived in this case, as Dr. Eden considers, purely on the question of the size of the baby.

I am, Sir, yours faithfully,

ROBT. A. HENDRY.

Department of Obstetrics and Gynaecology, University of Liverpool, June 23rd, 1923.

To the Editor of THE LANCET.

SIR,—With reference to Dr. T. W. Eden's paper on the Duration of Pregnancy in its Medico-Legal Aspect in your issue of June 16th, the following case appears to be worthy of notice:—

A. B., aged 42, whose last menstrual period occurred on Dec. 27th, 1896, was delivered on the night of Nov. 30th–Dec. 1st, 1897. The child, after craniotomy, washing out the brain, and removal of the liver and abdominal contents, weighed 14½ lb. It was necessary to remove the abdominal contents in order to get at the aftercoming head, which could not be induced to pass the brim. The duration of the pregnancy from the last menstrual period was 338 days.

The size of the child was, I think, almost a record; it was the physical equivalent of a child of 5 months old.

I am, Sir, yours faithfully,

WALTER C. SWAYNE.

Clifton, Bristol, June 23rd, 1923.

NURSES' REGISTRATION.

To the Editor of THE LANCET.

SIR,—In your Parliamentary Intelligence (June 23rd, p. 1293) you refer to the debate in the House of Commons on the Rules for the Registration of Existing Nurses under the Nurses' Registration Act, 1919, during which Dr. Chapple moved the amendment of the suggested Rule 9, 1, (g). My Council much regret that Dr. Chapple's speech in moving the amendment should have been so phrased as to convey to Members of Parliament the impression that his amendment was in accordance with the policy advocated by the College of Nursing. I am directed by the College Council to make it clear that the College is entirely opposed to Dr. Chapple's suggestions, the position being as follows: At the request of its members the Council of the College approached the

General Nursing Council in the letter quoted by Dr. Chapple, asking that the door of admission should be opened wider to the bona fide practising nurse, following which the General Nursing Council framed Rule 9, 1, (g), which admitted on their individual merits nurses in practice before 1900 and in 1919, and this Rule was entirely approved by the College Council as meeting the case of the older practising nurse. This approval was made clear in a typewritten statement, which was put into the hands of the medical Members of Parliament, including Dr. Chapple, on May 8th. It will be seen, therefore, that the College supports the Rule framed by the General Nursing Council, and strongly disagrees with the conditions laid down by Dr. Chapple for the admission of nurses to the Register.

I am, Sir, yours faithfully,

M. S. RUNDLE.

Secretary, College of Nursing, Ltd.

7, Henrietta-street, Cavendish-square, London, W. 1,
June 23rd, 1923.

THE FIRST "MENTAL HOSPITAL."

To the Editor of THE LANCET.

SIR,—During the Committee stage of the new Mental Treatment Bill in the House of Lords on May 30th the Earl of Onslow moved after Clause 8 to insert the following new clause:—

"Asylums provided by any public authority in England or Wales for lunatics or other persons of unsound mind shall hereafter be called mental hospitals and accordingly for references in any public or local Act or in any Order, regulations, or other document issued under any such Act to any such asylum shall be substituted references to mental hospitals."

Lord Onslow added that hitherto mental institutions had been described as asylums, and the word "asylum" had been associated with mental deficiency, and perhaps had contributed to the view that it was less a disease than an irremediable affliction. Nurses in mental institutions, alienists, and the Board of Control were, he said, all anxious that this change of name should be adopted. The amendment was agreed to.

This substitution of the word "mental hospital" for the word "lunatic asylum," which connotes both the moral evolution of the idea of treatment of the insane and the development of the machinery for their treatment, first occurred when the present mental hospital at Upper Warlingham was opened in 1903 under the aegis of the Croydon County Council, the first report being published in the following year during the mayoralty of Alderman C. C. Morland, J.P. Up to this time all public places for the reception of the insane in this country were called either "asylums" or "retreats," or the term applied was merely "hospital" without qualification, which made confusion with the general hospital for the treatment of the ordinary sick. This mental hospital, when it opened, was furnished with X ray rooms, pathological laboratory, operating theatre, and every modern appliance to abolish the old idea of asylum. Other institutions followed suit. The City of Cardiff, which opened a new asylum in 1904, called it the "Cardiff City Mental Hospital," and the third institution re-named was the City of London Asylum at Stone in 1905. In 1918 the London County Council rechristened their asylums "mental hospitals." Since then practically all the county and county boroughs in the country have re-named their asylums "mental hospitals."

To establish the priority of Warlingham I may quote from an account of the opening which appeared in the *Municipal Journal* of July 3rd, 1903:—

"With the advent of Pinel in France, and William Tuke of the York 'Retreat,' which still looks proudly down from the hill on Heslington Road, the last decade of the eighteenth century saw the restraint and ostracism giving place to humility, liberty, and recognition. In this direction the memories of Dr. Gardiner Hill, of the Lincoln Hospital, and Dr. Conolly, physician, of Hanwell, now one of the asylums of the County of London, will ever live. It was a happy idea to call this new institution at Warlingham, which

is replete with every up-to-date apparatus, a 'mental hospital.' There is some little mystery as to how it became so cognomened. The nomenclature, we believe, is really the copyright of the Medical Superintendent, who was adviser to the Council a year before it opened, and who is a progressive of the true type."

In the twentieth report of the hospital just published, the average recovery rate during the last ten years is given as 42 per cent., so that the purpose for which the hospital was opened is being fulfilled. The change of name means everything to the public, and more so to those who seek and need treatment therein. Coming generations will then grow up to call these institutions mental hospitals, or hospitals for the treatment of mental diseases, and never have the fear of them that their forefathers had.

I am, Sir, yours faithfully,

E. S. PASMORE, M.D. Lond.,
Medical Superintendent from the Foundation.
Croydon Mental Hospital, Upper Warlingham,
Surrey, June 24th, 1923.

THE RÔLE OF THE TOOTH-BRUSH.

To the Editor of THE LANCET.

SIR,—I agree with Sir John O'Connor in his tirade against the scrubbing of teeth with bristles. Until a year ago I used a tooth-brush twice a day and silk at nights. Since then I have discarded tooth-brushes in favour of careful friction with a lump of cotton-wool plus silk at nights and copious rinsing with plain water. My remaining 16 teeth have never before been so white or so comfortable, nor my gums so free from tenderness. If we could bring ourselves to "scrap the lot" of tooth-brushes in favour of cotton-wool, we should at least avoid many formidable evils due to them. I am not a dental surgeon, but only a

June 21st, 1923.

SEPTUAGENARIAN M.D.

Obituary.

WALTER D'ESTE EMERY, M.D., B.Sc.,
M.R.C.P. LOND.

Dr. Walter d'Este Emery died at the Red Cross Hospital, Brighton, on June 19th, at the early age of 53 years. Educated at Queen's University, Birmingham, and at St. Bartholomew's Hospital, he had a brilliant career as a student, graduating B.Sc. Lond. with first-class honours in physiology in 1892 before qualifying M.R.C.S., L.R.C.P. in 1894. He won the gold medal in medicine and obstetric medicine when taking the M.B. Lond. in 1896, together with a scholarship. A year later he proceeded to the M.D. degree, when he qualified for the gold medal, and became M.R.C.P. in 1918. His early appointments included those of house physician and ophthalmic and obstetric house surgeon at the Queen's Hospital, Birmingham, and assistant surgeon to the Birmingham Skin and Urinary Hospital, and in London that of assistant bacteriologist to the Royal Colleges of Physicians and Surgeons. Later he was appointed lecturer on pathology and bacteriology in the University of Birmingham, and in 1911 Hunterian Professor at the Royal College of Surgeons of England. Dr. d'Este Emery had also held the appointments of pathologist to the Paddington Green Children's Hospital, lecturer in general pathology at the London School of Medicine for Women, and director of laboratories and lecturer on pathology and bacteriology at King's College Hospital. He was the author of many scientific papers, and of books on "Immunity and Specific Therapy," "Clinical Bacteriology and Hæmatology," and "Bacteriological Diagnosis for Practitioners," which are well known, and his views on the Formation of Tumours: their Nature and Causation are well set out in a book on this subject. He also contributed articles to Cheyne and Burghard's "Manual of Surgical Treatment" and Rose and Carless's "Surgery."

With the death of Dr. d'Este Emery, the staff of King's College Hospital have lost a much valued friend

and guide in pathology. One of the earliest to take up clinical pathology as his main interest in life, Emery showed immediately after his appointment an originality in research and a keen critical judgment that made his room a rendezvous for the younger members of the staff, and although it must have added greatly to the burden of his work, he always showed a ready interest in discussing the various problems arising in the diagnosis and treatment of the hospital patients. His chief interests lay rather on the side of bacteriology and immunology, and his book on "Immunity and Specific Therapy" was one of the best and clearest expositions of the subject that could be placed in the hands of the clinician. He was also keenly interested in the problem of cancer and a strong supporter of the parasitic theory; his small work setting out the arguments in its favour is a model of cogent reasoning. At the hospital he was always engaged in strenuous work from a very early period after his appointment, and it is really astonishing that he should have found time and energy to write three volumes each requiring an immense amount of reading and thought. No doubt this constant activity was not without its effect on his health and may well have contributed to his untimely crippling and death. On the outbreak of war he took a commission in the R.A.M.C.(T.), with the result that his already excessive work was vastly increased, and it was quite obvious to his friends that this was acting very deleteriously on his never very robust physique. Nevertheless, he carried on with the utmost courage and at one time added to his burden by acting as director of the venereal department. In his later years at King's College Hospital he was tortured by constant headache and frequent insomnia, and finally the first breakdown came and precluded any further activity for some months. This was followed by a comparatively short return to his duties and then by unavoidable retirement from active life.

As a bacteriologist and serologist he was notable both for the accuracy of his results and for the well-balanced opinion that he always placed at the service of the staff. In morbid anatomy he was not so highly trained at the date of his appointment, but his keen interest and his desire to master every branch of his comprehensive subject led him to discuss all his most difficult problems with any colleague who had had special experience in morbid anatomy. He was thus in the later years of his activity able to give a first-class opinion on the microscopical appearances of diseased tissue. It was unfortunate that almost throughout the period of his appointment he was overburdened with routine work. With more leisure he might have been responsible for even more valuable research work, for he possessed a fine original mind and a great power of correctly judging the value of evidence. His ideals were high and he will long be remembered as a teacher, colleague, and eager worker.

THE LATE DR. D. EDWARDS OF CEMMAES.—Dr. David Edwards, who died recently, was one of the oldest medical practitioners in Montgomeryshire. He graduated in medicine and surgery at the University of Edinburgh in the year 1879, and for a time acted as a locum tenens at Llanrhaiadr, near Oswestry, before settling at Cemmaes Road, where he was in practice up to the time of his death. He was a justice of the peace for the county of Montgomery, medical officer for the Llanbrynmair and Cemmaes districts of the Machynlleth Union, and coroner for the Machynlleth district.

SMALL-POX IN ENGLAND AND WALES.—During the week ending June 16th, 79 cases of small-pox were notified in England and Wales, the distribution being as follows: Derbyshire, 1 (Heanor); Essex, 2 (West Ham); Gloucestershire, 58 (Gloucester 52, Gloucester R.D. 3, Stroud R.D. 1, Wheatenhurst R.D. 2); Nottinghamshire, 5 (Stapleford R.D.); Yorks North Riding, 1 (Thornaby-on-Tees); Yorks West Riding, 11 (Bentley-with-Arksey 5, Doncaster, 2; Doncaster R.D. 4); Monmouthshire, 1 (Risca). Groups of cases have since been reported from Warsop (Notts) and the Rhondda Valley, and scattered cases elsewhere. No deaths are reported.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Third Examination for Medical and Surgical Degrees held recently the following candidates were successful:—

Part I., Surgery, Midwifery, and Gynecology.—J. C. Ainsworth Davis, P. E. Bardsley, B. Broadbent, G. M. Brown, J. T. Burrell, N. E. Chadwick, W. E. F. Davidson, G. S. W. Evans, M. W. H. Evans, L. S. Fry, T. S. Goodwin, C. J. P. Grosvenor, H. E. Harris, G. T. Henderson, E. G. Holmes, J. W. W. Jepps, A. H. Johns, M. E. Kennedy, L. P. Lockhart, C. A. Lupton, R. J. Lythgoe, G. C. Millis, A. C. Mowle, E. B. Murrell, L. R. W. Price, R. J. V. Pulvertaft, J. Russell, C. E. G. Smith, R. W. Smith, J. D. M. Stewart, J. H. G. Thompson, E. R. Weaver-Adams, M. H. Webb-Peploe, R. Whillis, L. E. H. Whitby, and R. N. P. Wilson.

Part II., Medicine, Pathology, and Pharmacology.—B. Broadbent, E. B. Brooke, G. H. Caiger, D. H. Cole, G. K. Cooper, E. J. Crisp, W. E. F. Davidson, W. Edwards, L. E. Frazer, L. B. Hartley, M. E. Kennedy, L. Lawn, S. Orchard, A. V. Pegge, L. R. W. Price, J. Russell, J. M. Scott, A. G. Story, C. Starton, E. Tagoe, C. G. Taylor, G. D. Thomson, A. S. H. Walford, L. E. H. Whitby, and R. N. P. Wilson.

UNIVERSITY OF DURHAM.—At the Third Examination for the Degrees of Bachelor of Medicine and Bachelor of Surgery the following candidates were successful:—

Materia Medica, Pharmacology and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology.—Charles W. Arnot, Drummond R. F. Bertram, Frank H. Blackburn, Abraham Brodie, John Brown, Alfred Charlton, Nora E. Colman, Norman Davidson, James W. Dickinson, Douglas Ewart, John R. Garson, Alan Gray, Eric V. Griffiths (second-class honours), John T. Holliday, Austen H. Holmes, Sinclair Hughson, Marjory G. T. Jacka, Maurice H. Jones, Bernard Kaplansky, Harold Levy, Fenwick Lishman, Donald W. McLaren, Richard A. Pallister, Ethel G. Potts, Arthur Purvis, Charlotte B. Schofield (second-class honours), Stuart C. Stonier, Walter Toward, Charles C. Ungley (second-class honours), William S. Walton, Reginald Wear, and James Y. Woodhouse.

UNIVERSITY OF BRISTOL.—At examinations recently held the following candidates were successful:—

FINAL EXAMINATION FOR DEGREES OF M.B., CH.B.
Part II., (completing examination).—Francis H. Bodman (second-class honours), Constance L. Griffiths (second-class honours), Dorothy Stanley, and Idris Williams.

Part I., (including Forensic Medicine and Toxicology).—Ernest R. Clutterbuck, Edward B. Eadie, John A. James, Frederick G. Jenkins, Frank Langford, George S. Mundy, and Arthur S. Prowse.

Part I., only.—Robert H. Dummett, and Kenneth F. Platt.
Forensic Medicine and Toxicology only.—Helen M. Dixon.

FINAL EXAMINATION FOR DIPLOMA IN DENTAL SURGERY.

Vincent E. N. Allen, Horace N. V. Barnes, Stuart H. Bedford, Alan S. C. Boulter, Maurice P. Browning, Arthur H. Butcher, Robert G. Butterworth, Hugh P. Evans, George Holt, Arthur R. Hutchings, Cledwyn Lewis, Frederick C. G. Lewis, John C. W. Lewis, Reginald C. Price, James F. Rigg, John S. Roberts, William H. Simpkins, Charles E. Smith, Edgar K. Tratman, Kathleen M. Watson, and Frederick C. Winter.

UNIVERSITY OF GLASGOW.—At the graduation ceremony on June 21st the following degrees were conferred:—

M.D.—Grace H. Anderson (honours), J. B. D. Galbraith (high commendation), B. S. Nicholson (high commendation), Lydia I. H. Torrance (commendation), C. Averill, A. D. Blakely, L. L. Fyfe, A. Macphail, J. M. Melvin, and G. W. Ronaldson.

D.Sc.—Muriel Robertson.

LL.D. (Hon.)—Sir Walter Morley Fletcher, Prof. Graham Lusk, and Dr. Andrew Maitland Ramsay.

UNIVERSITY OF MANCHESTER.—The Council on June 20th appointed Dr. H. S. Raper as Brackenbury Professor of Physiology and Director of the Physiological Laboratories from September next. Dr. Raper is at present professor of physiology and biochemistry in the University of Leeds. He was elected Ackroyd scholar in Yorkshire College in 1902 and was University Scholar in the Victoria University in 1903. From 1904-07 he held an 1851 Exhibition Scholarship. After a year as a demonstrator in physiology at Leeds he was appointed lecturer in pathological chemistry in the University of Toronto in 1910, remaining there until his return to Leeds in 1913 as lecturer in physiological chemistry. He was appointed to his present post in 1917. During the war Dr. Raper was engaged in research work on protection against poison-gas, and from 1918 was head of the Anti-gas Department, with control of the factories in which respirators were made. He is at present retained by the War Office in an advisory capacity on physiological questions arising in connexion with chemical warfare.

Mr. T. M. Bride has been appointed Clinical Lecturer in Ophthalmology, and Mr. David Stewart Assistant Lecturer in Anatomy. Mr. G. V. Ashcroft and Miss E. R. A. Cooper have been appointed Demonstrators in Anatomy, and Mr. W. H. Wood Tutor and Secretary to the Faculty of Medicine.

UNIVERSITY OF LONDON.—At a meeting of the Senate, held on June 20th, Mr. H. J. Waring was re-elected Vice-Chancellor for the year 1923-24. Prof. Frederick Wood Jones was appointed from Sept. 1st next to the University Chair of Anatomy tenable at St. Bartholomew's Hospital Medical College. He has been demonstrator in anatomy at the London Hospital, senior demonstrator and lecturer in anatomy at Manchester, senior demonstrator in anatomy at St. Thomas's Hospital, and head of the department of anatomy at the London School of Medicine for Women, in respect of which post the Senate conferred on him, in 1914, the title of professor. Since 1919 he has been professor of anatomy in the University of Adelaide. He is the author of "Arboreal Man," "The Principles of Anatomy as Seen in the Hand," and numerous other publications.

Dr. R. J. S. McDowall was appointed from August 1st next to the University Chair of Physiology tenable at King's College. During the war he served in the R.A.M.C. with the Egyptian Expeditionary Force. He has been lecturer in physiology at Edinburgh; and since 1921 he has been lecturer in experimental physiology and experimental pharmacology at Leeds. He is the author of publications on mammalian muscle, pulmonary circulation, and numerous other physiological subjects.

Mr. Gilbert Stead, M.A. Camb., was appointed as from August 1st next to the University Readership in Physics tenable at Guy's Hospital Medical School. He obtained a first class in both parts of the Natural Sciences Tripos, and has been since 1910 assistant demonstrator in the Cavendish Laboratory, except during the war, when he was engaged on research in wireless telegraphy for the Admiralty at Portsmouth. He is the author of numerous publications embodying the results of research on the passage of electricity through gases.

FIFTH ITALIAN CONGRESS OF MEDICAL RADIOLOGY. The Congress will be held at the University of Palermo on Oct. 18th-21st, under the auspices of the Società Italiana di Radiologia Medica and of the Minister of Public Instruction. The honorary president of the Congress will be Senator Prof. O. M. Corbino; president, Prof. G. Scaduto. Among the subjects dealt with will be Roentgenotherapy of Cutaneous Diseases (Prof. Rossi, of Parma), Pneumo-Radiography (Prof. Gortan, of Trieste), and Radiographic Diagnosis of Diseases of the Urinary Tract (Prof. Boidi Trotti, of Turin). An exhibition of apparatus will be held during the Congress. The secretary of the Congress is Dr. Salvatore Sgroi, to whom all communications should be addressed at Via Alloro, 58, Palermo, Sicily.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary council meeting held on June 14th, Sir Anthony Bowlby, the President, being in the chair, Mr. J. Howard Mummery was introduced, and after signing the by-laws and making the required declaration was admitted a Fellow of the College.—A report was read from the Court of Examiners respecting candidates found qualified for the Diploma of Fellow and Diplomas were granted to 24 candidates mentioned in the report.—A report was read from the Board of Examiners in Dental Surgery respecting candidates found qualified for the Licence in Dental Surgery and licences were granted to 76 candidates mentioned in the report.—The following were elected Members of the Board of Examiners for the Fellowship for the ensuing year: Anatomy: J. Ernest Frazer, G. Gordon-Taylor, W. F. Haslam, W. Wright; Physiology: David de Souza, John Mellanby, Frangcon Roberts, and A. Rendle Short.—The following were elected Examiners under the Conjoint Board for the ensuing year: Elementary Biology: J. P. Hill, T. W. Shore; Anatomy: H. A. Harris, David Hepburn, John Basil Hume; Physiology: C. Lovatt Evans, H. E. Roaf; Midwifery: Eardley L. Holland, Hubert C. Roberts, G. D. Robinson, and Donald W. Roy; Public Health: Part I., Sir Fredk. W. Andrewes; Part II., Francis J. Stevens; Tropical Medicine and Hygiene: George C. Low, H. B. G. Newham; Ophthalmic Medicine and Surgery: Part I., H. Willoughby Lyle and Sir J. Herbert Parsons; Part II., Malcolm D. Hepburn; Psychological Medicine: Sir Fredk. Mott.—A report from the Committee of Management was read and approved recommending the institution of a Diploma in Laryngology and Otology, but the report will have to be approved by the Royal College of Physicians before it comes into force.—A letter was read from Mr. F. F. Burghard resigning his membership of the Court of Examiners, such resignation to take effect on the completion of the pass examination for the Membership in July. The resignation was accepted and the President reported that the vacancy would be filled up at the ordinary council on July 31st.—The President announced that Mr. N. G. Bennett's term of office on the Board of Examiners in Dental Surgery would expire on July 25th next, and that the vacancy thus occasioned would be filled up at the ordinary council on July 31st.

FOOD EDUCATION SOCIETY.—The Society has recently issued a useful leaflet for the guidance of housewives, entitled "How to Choose Sugar." This leaflet, which is a reprint of an article appearing in *National Health* in April last, discusses various forms of sugar with a view to removing the widespread misconception relating to them. Raw sugar is described as unfit for direct human consumption; "direct consumption" sugar (Demerara or brown sugar, also called by other names) is not much superior to raw sugar; "plantation white" sugar, purer than either of the foregoing, is more wholesome, but retains colouring matter, which is bleached but not removed. Beet-sugar, when properly refined, is quite as good as refined cane-sugar. The latter is "an article free from all impurity to an extent unapproached by any other foodstuff made in such large quantity," attaining a purity of 99.9 per cent., and being better for all purposes in direct ratio to its purity. The leaflet may be obtained (post free, 1½d.) from the Society, 329, Vauxhall Bridge-road, London, S.W. 1.

MENTAL HOSPITAL MATRONS' ASSOCIATION.—On June 14th a meeting was held in the Board Room of Bethlem Royal Hospital, London, to discuss the formation of a Mental Hospital Matrons' Association. The meeting was a representative one, matrons of mental hospitals throughout the country being present. The objects of the proposed Association are: (1) To enable members to take counsel together on matters affecting their profession, and to exchange ideas as to the present system of nursing in our mental hospitals, and as to how this system could be further advanced and improved, both in the interests of the nursing staff and to the advantage of the patients under their care. (2) To maintain the honour and further the interests of the mental nursing profession. Miss Macaulay, matron of the Kent County Mental Hospital, Maidstone, said that an organisation of this kind should prove helpful and beneficial to nurses in hospitals and those engaged in private nursing. Meetings could be held at the various hospitals, say every three months, by the permission and invitation of the medical superintendent and matron. The Matrons' Association would be able to speak with authority on behalf of mental nurses generally and to bring matters specially affecting them to the notice of the Mental Representatives on the General Nursing Council. The resolution to form a Mental Hospital Matrons' Association was carried unanimously, and a vote of thanks was passed to the *Nursing Times* for its help in promoting the meeting and its encouraging interest in mental nurses.

CONFERENCE ON INFANT WELFARE.—The programme of conference to be held at Carnegie House, 117, Piccadilly, London, W., on July 2nd, 3rd, and 4th, has been issued by the National Association for the Prevention of Infant Mortality and National Baby Week Council under whose auspices it will be held. On July 2nd Dr. G. F. Still will take the chair. Mr. Neville Chamberlain will give a presidential address, and Dr. J. S. Fairbairn, Mr. Eardley Holland, Dr. Eric Pritchard, Dr. R. C. Jewesbury, Prof. A. L. McIlroy, Dr. Donald Paterson, and others will discuss the Causal Factors of Infant Mortality up to One Month of Age (ante-natal, intra-natal, and neo-natal) and their Prevention. In the afternoon, Dr. Janet M. Campbell presiding, a debate on the Value of Maternity Homes in a Maternity and Child Welfare Scheme will be opened by Dr. W. Allen Daley, Mr. A. Leyland Robinson, and Miss Wishart. At 5 p.m. a meeting of the General Council of the Association of Infant Welfare and Maternity Centres will be held, when a discussion on Should Out-relief be Given in Cash or in Kind, with special reference to Dietaries for Children under Five will be opened by Dr. Stella Churchill and Mrs. Duncan Harris. At 7 p.m. Mr. R. C. Elmslie will give a lecture on the Prevention and Treatment of Crippling in Children, and at 8 p.m. Dr. C. E. Wallis will give an address on the Preservation of the Teeth (illustrated by lantern slides).—On the 3rd, Mr. H. O. Stutchbury presiding, Dr. W. G. Willoughby, Dr. Mabel Brodie, and Dr. E. R. Fothergill will discuss the Scope, Staffing, and Administration of Maternity and Child Welfare Centres. In the afternoon, under the chairmanship of Dr. J. W. Robertson, a debate on Is It Advisable in Urban Areas to Combine the Functions of the Health Visitor with those of other Officers of Local Authorities? will be opened by Dr. E. W. Hope, Dr. F. E. Wynne, and Miss Sayle. At 5 p.m. the annual general meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health will be held, and a discussion on the Feeding of Children from 5 Years of Age will be opened by Prof. E. Mellanby. At 7 p.m. Mr. Bishop Harman will lecture on the Prevention of Blindness in Young Children, and at 8 p.m. Dr. S. G. Moore will give an account of some special work in Huddersfield for the reduction of infant mortality.—On the 4th, in the morning, Dr. Constance Ellis will preside. The subject for debate will be the Maternity Convention passed by the Washington Convention, 1919, and Miss Margaret

Bondfield and Dr. Rhoda Adamson will contribute papers. In the afternoon, Sir Arthur Stanley presiding, a debate on Housing in Relation to Infant Welfare will be opened by Dr. Marion Cockerell, Miss M. M. Jeffery, and Miss S. M. Bushell. At 7 p.m. Dr. Evelyn Saywell will lecture on the Psychology of Infancy, and at 8 p.m. Miss Norah March on the Efficiency of the Infant Welfare Worker: A Problem of Physiology and Psychology. Visits to various institutions connected with infant welfare will be paid during the Congress. Further particulars of the Congress may be obtained from the Secretary at 117, Piccadilly.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The annual meeting of the Association will be held on July 9th to 13th under the presidency of Lieut.-Colonel E. Goodall, at 11, Chandos-street, Cavendish-square, London, W. 1, and 1, Wimpole-street, London, W. 1.

HOSPITALS AND LEGACY DUTY.—On June 26th a deputation waited upon Sir William Joynson-Hicks, Financial Secretary to the Treasury, in support of the proposal that legacies to hospitals should be exempted from legacy and succession duty. It was contended that the scheme for the re-establishment of voluntary hospitals contained in Lord Cave's Report should be treated as a whole, and that the proposal that legacies to hospitals should be exempted from legacy duty was an integral part of it. Sir William Joynson-Hicks promised to report the opinions of the deputation to the Prime Minister. The deputation was introduced by Dr. Macnamara, M.P., and included the following:—

Members of Parliament: Lord Ednam, Major the Hon. Edward Cadogan, Colonel Maurice Alexander, K.C., and Dr. W. A. Chapple.

Representatives of King Edward's Hospital Fund for London: Lord Somerleyton, Lord Stuart of Wortley, Lord Mildmay of Flete, Sir William J. Collins, Sir Basil Mayhew, and Mr. H. R. Maynard (secretary).

Representatives of the British Hospitals Association: Lord Knutsford, Lord Hambleden, Lord Stanmore, the Hon. Sir Arthur Stanley, Mr. Thomas Hayes, and Mr. J. Courtney Buchanan (honorary secretary).

The following hospital representatives were unavoidably prevented from attending: Lord Burnham (King Edward's Hospital Fund), Mr. Wade Deacon, of Liverpool, Sir Henry Hadlow, of Sheffield, and the Rev. G. B. Cronshaw, of Oxford (British Hospitals Association).

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual dinner of this Society brought a large company to the Café Monico on the evening of June 19th. The occasion was distinguished by the presentation to Sir Clifford Allbutt of the Society's triennial gold medal. In accepting this honour the venerable professor made a speech which for the vigour of its delivery and for the complete familiarity which it showed with the latest developments of medical and ancillary science must have put envy into the hearts of even the youngest and most brilliant of his hearers. The toast list was a long one and we cannot linger over the many wise and entertaining observations which it called forth. Mention must be made, however, of the Cavendish lecturer, Dr. Henry Head, whose witty reply was equal to the concise and eloquent speech in which Sir Humphry Rolleston proposed his health. Sir Arbuthnot Lane, in proposing the Society's health with that of its President, Dr. A. G. Wells, urged the Society and the hospital with which it is associated to march shoulder to shoulder with other post-graduate schools and make London the premier city of the world for post-graduate instruction.

STUDY-TOUR OF SPAS IN JURA AND SAVOY.—The seventeenth Voyage d'Etudes Médicales tour will take place under the scientific direction of Prof. Paul Carnot and Prof. agrégé Rathery from Sept. 9th to 22nd. The meeting place is Besançon. Thence visits will successively be made to La Mouillière, Salins-du-Jura, Divonne, with a diversion to visit the Swiss Universities of Geneva and Lausanne; thence to Evian, Thonon, Chamonix, Saint-Gervais, Annecy, Aix-les-Bains, le Revard, Challes, Allevard, Moutiers-Salins, Brides, Pralognan, Uriage, Grenoble, St. Pierre de Chartreuse, La Motte-les-Bains, La Grave, and le Lautaret; thence to Lyons, where after visiting the school of medicine and the town sights, the party will break up. This tour is reserved primarily for doctors and medical students, who may be accompanied by wife or daughter up to 15 per cent. of the total membership. The cost from Besançon to Lyons is fixed at 790 francs, all included. A reduction of 50 per cent. will be granted on the French railways to the meeting place and from the place of dispersal to the frontier station. Further information may be obtained on application personally or by post to Mme. Juppé-Blaise, representative of the French spas, at the French Touring Office, 56, Haymarket, London, S.W. 1.

DONATIONS AND BEQUESTS.—By the will of the late Mr. Charles Beasley, of The Cottage, Abbey Wood, Kent, the testator left £5000 to the Woolwich Memorial Hospital

for the endowment fund: £1000 each to the Woolwich and Plumstead Nurses' Association for the endowment fund, Woolwich and Plumstead Cottage Hospital, Home for Mothers and Babies, Wood-street, Woolwich, Middlesex Hospital (for the cancer research fund), St. Bartholomew's Hospital, Guy's Hospital, the London Hospital, Charing Cross Hospital, Miller Hospital, Greenwich, the Brompton Hospital for Consumption, the Cancer Hospital, Fulham-road, the Hospital for Sick Children, Great Ormond-street, the Royal Waterloo Hospital for Children, the Surgical Aid Society, and St. Dunstan's Hostel for Blinded Soldiers and Sailors.—The late Mr. John Fleming, of Woodside-crescent, Glasgow, left by will £2000 each to the Glasgow Royal Infirmary, the Western Infirmary, Glasgow, the Victoria Infirmary, Glasgow, and the East Park Home for Infirmary Children, and £1000 to the Royal Hospital for Sick Children, York Hill, Glasgow.—The late Mr. Arthur Worthington, of The Hydro, Neville-crescent, Llandudno, who left property of the gross value of £35,967, bequeathed, after certain small legacies have been paid, two-fiftieths to the Infirmary for Children, Liverpool, and one-fiftieth each the Royal Infirmary, Royal Southern Hospital, St. Paul's Eye Hospital, Eye and Ear Hospital, and the Hospital for Cancer.—The late Sir Joseph Walton, of Rushpool, Saltburn, and of Middlesbrough, Yorks, among other bequests, has left a sum of £20,000 and a sum of £5000 (less a charge for annuities amounting to £250 per annum) on trust to apply the income for the ten years following his death, as to: four-tenths to the Beckett Hospital, Barnsley, for the children's ward; two-tenths to the North Riding Infirmary, Middlesbrough, for the children's ward; two-tenths to the North Ormesby Cottage Hospital, for the children's ward; two-tenths to the Joe Walton Boys' Club, Faversham-street, Middlesbrough, all in memory of his son Joseph, and with remainder to his residuary estate. He also left, in memory of his son Joseph, £250 a year for ten years, to be divided between certain institutions, including the North Ormesby Cottage Hospital, the Beckett Hospital, Barnsley, Industrial School Nurses' Home at Middlesbrough, and the Barnsley Nursing Association.—Under the will of the late Mr. William Strickland, of Graveleythorpe, Halton, near Leeds, the testator left, subject to certain life interests, £1000 and 1000 shares in John Barran and Sons, Ltd., between the Leeds General Infirmary and the Women's and Children's General Hospital; £100 to the Leeds Public Dispensary, and £100 to St. John's Homes for Incurables, Seorton, and the residue (after certain private bequests) to such institutions, having for their object the aid of crippled or disabled soldiers, as the executors think best.—The directors of Messrs. Brunner Mond and Co. have decided to make a jubilee gift of £1000, and have sent a cheque for that amount, to the Victoria Infirmary, Northwich.—The Chelsea Hospital for Women has received £281 from the estate of the late Miss Giacomelli, a former patient of the hospital.—The Manchester Royal Infirmary has received from the Manchester, Salford and District Joint Committee of Hospital and Saturday Fund £1568.—The Lord Mayor of Manchester's 2,000,000 Shilling Hospital Fund has reached over £30,000. A cheque for £905 has been received from the management of the Housekeeping Exhibition, and the directors of the Ship Canal have voted £250 to the fund.

AMBULANCE FACILITIES.—The great development in recent years of the home service ambulance scheme is well shown in the report of the Norfolk branch of the British Red Cross Society for 1922. The county director considers that many lives are saved each year by this service owing to the improved method of transit of serious medical and surgical cases. There are eight ambulance stations in the County of Norfolk: at Cromer, Downham Market, East Dereham, Hunstanton, Norwich, King's Lynn, Thetford, and Great Yarmouth. In 1919 the number of patients dealt with was 358 and the mileage covered 6193. The corresponding figures in 1920 were 701 and 16,030; in 1921, 676 and 13,572; and in 1922, 832 and 14,796, so that in four years no less than 2567 cases have been dealt with and 50,592 miles covered. Last year the Norwich car carried 190 patients and travelled 5622 miles, while the Yarmouth car carried 329 patients and travelled 1271 miles.

WORLD'S DAIRY CONGRESS IN U.S.A.—The Congress will be held from Oct. 2nd to 10th at Washington, D.C., Philadelphia, Pa., and Syracuse, N.Y. The provisional programme includes, on Oct. 2nd and 3rd, the official welcome and opening of the Congress by high Government officials of the United States, addresses by members of the President's Cabinet and distinguished speakers from several countries, three formal sessions of the Congress, visits to dairy division laboratories, a dairy experimental farm, &c., and various social functions. At Philadelphia, on the 4th, the Congress will consider the work of the National Dairy Council. At Syracuse, N.Y., the Congress will continue to sit from the 5th to 10th, but delegates will participate in the opening of the seventeenth annual National Dairy Exposition, and will have the opportunity of making various tours

of inspection; numerous social activities will take place under the auspices of the Syracuse civic and dairy bodies. Owing to the full programme of Oct. 2nd and 3rd, persons wishing to make extended visits to Government laboratories and places of interest in Washington will find it advantageous to come in advance of the opening of the Congress. Full information may be had on application to the World's Dairy Congress Association, Inc., Star Building, Washington, D.C., U.S.A.

The Services.

INDIAN MEDICAL SERVICE.

THE annual dinner in London of officers of the Indian Medical Service was held at the Trocadero Restaurant on June 20th. Major-General Sir W. R. Edwards, K.C.B., K.C.I.E., being in the chair. The only guests present were Mr. Austin Low, C.I.E., and representatives of the *British Medical Journal* and *The Lancet*. The officers present numbered 96, as follows:—

Major-Generals: Charles, Sir R. H., G.C.V.O., K.C.S.I.; Deare, B. H., C.I.E.; Giffard, Sir G. G., K.C.I.E., C.S.I.; Grainger, T., C.B.; Harris, G. F. A., C.S.I.; Hendley, H., C.S.I.; and Smith, J. B., C.B., C.I.E.

Colonels: Banatyala, Sir H. E., C.S.I.; Chapman, P. F., C.I.E.; Close, J. K.; Crimmin, J., V.C., C.B., C.I.E.; Garvie, J.; Granger, T. A., C.M.G.; Green, C. R. M.; Macnab, A. J., C.B., C.M.G.; Pratt, J. J.; Quayle, W. A.; Smith, H. Austen, C.I.E.; Stodart, T., C.I.E.; Turner, R. G., C.M.G., D.S.O.; and Wimberley, C. N. O., C.M.G.

Lieut.-Colonels: Alcock, A., C.I.E.; Alpin, W. G. P., O.B.E.; Anderson, J., C.I.E.; Blenkinsop, F. L.; Calvert, J. T., C.I.E.; Crawford, D. G.; Graham, J. D., C.I.E.; Crawford, J. M., O.B.E.; Coppinger, W. V., D.S.O.; Dawes, C. D.; Donovan, C.; Duer, C.; Gill, C. A.; Hamilton, J. A., C.M.G.; Hudson, C. T., C.M.G.; Hugo, E. V., C.M.G.; Hulbert, J. G.; James, C. H., C.I.E.; James, S. P.; Jordan, J. G.; Kirkpatrick, H.; Kunhardt, J. C. G.; Lane, W. B., C.I.E., C.B.E.; Lloyd, R. A., D.S.O.; Masson, J.; Mell, F. O. N., C.I.E.; Miller, A.; Mitter, R. K.; Mulroney, T. R.; O'Kinealy, F., C.I.E., C.V.O.; O'Meara, E. J., O.B.E.; Prall, S. E.; Price, R. H.; Rainier, N.; Roberts, Sir J. R., C.I.E.; Rogers, Sir L., C.I.E.; Saigol, R. D.; Shaw, W. S. J.; Smith, G. M. C., C.M.G.; Lane, Clayton; Melville, C. W. F.; Rost, E. R., O.B.E.; Smith, H., C.I.E.; Steen, R.; Standage, R. F., C.I.E.; Street, A.; Thomson, C.; Thornhill, W. H.; Walsh, J. H. Tull; Walton, H. J.; Walker, J. N.; Warlicker, D. P.; Watson, J. W., C.I.E.; Wortabet, H. G. L.; and Younan, A. C.

Majors: Clifford, R. C., D.S.O., M.C.; Brown, H. C., C.I.E.; Cameron, A., O.B.E.; Hughes, T. A.; Hume, N. H.; Lloyd, R. B.; Lynn, G. R., D.S.O.; Mills, P. S.; Munro, A. C.; Thakur, K. S.; Tressider, A. G.; White, M. F., O.B.E.; and Wells, R. L.

Captains: Albuquerque, J. W. F.; Basu, P.; Covell, G.; Khan, M. M.; McIver, C.; McRobert, G. R.; and Thomas, D. R.

ROYAL NAVAL MEDICAL SERVICE.

Temp. Surg.-Lt. (Dental) C. Williams is transferred to permanent list in rank of Surgeon-Lieut.

ROYAL NAVAL VOLUNTEER RESERVE.

G. A. Clark is entered as Surg.-Lt. on the permanent list.

ROYAL ARMY MEDICAL CORPS.

Maj. J. MacKenzie relinquishes the temp. rank of Lt.-Col. Temp. Capt. W. M. M. Jackson relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

General List: Capt. L. H. D. Castle (R.A.R.O.) to be Capt. for service with Imperial Service College Contingent, Junior Div., O.T.C.; Lt. J. G. B. Coleman to be Capt. (prov.).

Capt. T. S. Worboys, having attained the age limit, is retired, and is granted the rank of Maj.

L. F. O'Shaughnessy to be Lt.

General Hospitals: Capt. A. A. Burrell, B. A. W. Stone, and W. Y. Woodburn relinquish their commns. and retain the rank of Capt.

Maj. H. E. Counsell, having attained the age limit, is retired, and retains the rank of Maj.

Capt. W. H. Nutt, having attained the age limit, is retired, and retains the rank of Capt.

Edinburgh University Contingent (Medical Unit) Senior Div.: Lt. W. R. Martine to be Capt.

TERRITORIAL ARMY RESERVE.

Lt.-Col. W. Kirkpatrick, having attained the age limit, is retired, and retains the rank of Lt.-Col.

Sanitary Companies: Capt. S. J. Clegg relinquishes his commn. and is granted the rank of Maj.

ROYAL AIR FORCE.

J. A. Quin is granted a short service commission as a Flight Lt.

Parliamentary Intelligence.

HOUSE OF COMMONS

WEDNESDAY, JUNE 20TH.

Sexual Offences against Children.

Major PAGET, in asking leave to introduce a Bill "to provide for the better protection of young children," said it consisted of one clause only, which was: "Any person who shall be guilty of a felony or misdemeanour under Section 4 or 5 of the Criminal Law Amendment Act, 1885, and be convicted thereof, may at the discretion of the Court and in addition to any term of imprisonment in the said Act provided be sentenced in respect of the said offence to be once privately whipped. The number of strokes and the instrument with which they are to be inflicted shall be specified by the Court in the sentence." Section 2 of Section 4 of the Act of 1885 laid down that for these sexual offences against young children under 13 a youth of 16 might be whipped. The Bill, he said, merely extended this to those of a more advanced age, who should know considerably better. The Bill aimed at the protection of young and innocent children, and he was afraid that these offences against them were distinctly on the increase. One or two mental degenerates might get beaten instead of being put in an asylum, but if it protected only four or five innocent little girls from outrage he thought that they could be quite content and happy in their consciences.

Mr. BUCHANAN, while agreeing that such crimes should be condemned, thought that the Bill was not a proper method of preventing them. He would sooner that the Bill compelled the person committing such a crime to abstain from human society for all time rather than he should be beaten. Whipping was not so much a disgrace to the person whipped as to the person who did the whipping.

The Bill was read a second time without a division.

Transference of Panel Patients.

Mr. EMLYN-JONES asked the Minister of Health if his attention had been drawn to the practice of certain medical practitioners of transferring their panel patients to other doctors for a monetary consideration regardless of the wishes of the patients themselves, and whether he would take steps to prevent such a practice being pursued.—Mr. NEVILLE CHAMBERLAIN replied: The hon. Member is under a misapprehension. Under the Medical Benefit Regulations no insured person can be transferred to any practitioner against his wishes, and his rights in this respect are in no way affected by any arrangements which doctors may make with one another for the sale of the goodwill of a practice.

Mr. EMLYN-JONES: Is it not a fact that panel patients have to give six months' notice to transfer, and that in many cases they are transferred to another practitioner against their will before the expiry of the requisite notice?

Mr. CHAMBERLAIN: It still remains the fact that he cannot be transferred against his wish.

Sir KINGSLEY WOOD: Is the right hon. gentleman aware that there is a large body of opinion that has strong objections to this practice, and is this one of the matters which is going to be considered by him and the special committee of the British Medical Association? Can the right hon. gentleman inform the House whether he proposes to make a statement to the House following this conference with that special committee?

The SPEAKER: These questions should be put on the paper.

Small-pox in the Army.

Mr. LEACH asked the Under Secretary of State for War for the figures indicating an increase in small-pox in the army consequent on the suspension of the vaccination recruiting regulation, giving also the attack-rate per million strength.—Lieut.-Colonel GUINNESS replied: I am not at present in a position to give the attack-rate per million strength, but in France there were no cases of small-pox before 1916 and 12 cases subsequently. In Iraq there were 2 cases in 1916, 364 in 1917, and 597 in 1918. Of the cases in Iraq, about 84 per cent. occurred amongst men who had not been vaccinated or re-vaccinated since enlistment.

Medical Men at Ministry of Health.

Mr. BECKER asked the Minister of Health how many medical men were employed at the Ministry of Health and regional headquarters on a sessional basis, and if, owing to the urgent need of economy, he would consider placing some of these on the salaried staff.—Mr. NEVILLE CHAMBERLAIN replied: There are 54 medical men employed in the work of the regional staff on a sessional basis. There would be no economy in placing any of these on the salaried staff.

Mr. BECKER asked the Minister of Health how many retired-pay medical officers who were in receipt of pensions from the army, &c., were employed in salaried positions in

the Ministry of Health, and if he would recommend that these officers be replaced by some of the highly experienced ex-Service men who were not so placed.—Mr. NEVILLE CHAMBERLAIN replied: Three medical officers of the Ministry of Health are in receipt of retired pay; two of these officers are established civil servants and the unestablished officer possesses special qualifications in connexion with venereal disease. I am unable to adopt the suggestion contained in the latter part of the hon. Member's question.

Hospitals and Nurses' Training Rules.

Mr. FOOT MITCHELL asked the Minister of Health whether he was aware of the serious position in which the smaller hospitals had been placed in consequence of the regulations of the General Nursing Council regarding the training of nurses, which had increased the difficulty of obtaining probationers in such hospitals and were adding seriously to the financial difficulties with which they had to contend; and whether he would approach the General Nursing Council with a view to some modifications being made in their regulations in order to overcome these difficulties and enabling nurses trained in such hospitals to be qualified for registration after passing the central examination or otherwise.—Mr. NEVILLE CHAMBERLAIN replied: I have not received representations in this sense. It is open to any hospital which is refused approval by the General Nursing Council to appeal to me, and no such appeal has been made. I see no reason for adopting the suggestion contained in the last part of the question.

Deaths from Pregnancy or Childbirth.

Mr. TURNER asked the Minister of Health what number of women died through pregnancy or childbirth in England and Wales during the past year.—Mr. NEVILLE CHAMBERLAIN replied: The number of deaths classed to pregnancy and childbirth in 1922 was 2971. In the same year the number of deaths associated with childbirth but attributed to other causes was 1051.

New Houses in England.

Mr. GILBERT asked the Minister of Health whether he could state, approximately, the number of new houses which had been built and completed for occupation in each of the years 1920, 1921, and 1922 in England; and could he also state how many new houses were under construction in the same area at the present time.—Mr. NEVILLE CHAMBERLAIN replied: During the three years 1920, 1921, and 1922 the number of houses completed in England and Wales under State-aided housing schemes was 15,700, 86,669, and 88,976 respectively. Statistics are not available showing the total number of houses erected during the same period without State aid. On June 1st, 8019 houses were in course of construction under the State-assisted scheme authorised by the Housing, Town Planning, &c., Act, 1919. In addition, schemes for over 13,000 houses have been authorised which will rank for assistance under the new Bill if it becomes law. According to a return recently obtained from certain local authorities, 14,763 houses had been completed by private builders since the end of September last and 17,693 houses were in course of construction without State assistance.

THURSDAY, JUNE 21ST.

Birmingham Hospital Fire.

Sir EVELYN CECIL asked the Minister of Pensions what steps had been taken with reference to the promised inquiry into the cause of the fire at the Pensioners' Hospital, Highbury, Birmingham, on June 13th.—Major TRYON replied: I have appointed the Parliamentary Secretary to the Ministry (Captain Craig) to be Chairman of a Committee of Inquiry into this regrettable matter, the other members being: Mr. G. Topham Forrest, F.R.I.B.A. (architect to the London County Council); Mr. A. R. Dyer, A.M.I.C.E. (chief officer of the London Fire Brigade); Mr. H. Baines, O.B.E. (chief engineer, Office of Works); Dr. H. Lightstone, D.S.O., M.C. (headquarters inspector, Ministry of Pensions); and Mr. T. A. Pole, A.R.I.B.A. (architect to the Ministry of Pensions). The Committee's terms of reference are: "To ascertain the cause of the fire which recently took place at Highbury Hospital and to consider whether any and, if so, what precautions are required to prevent similar accidents in future at hospital buildings for which the Ministry is responsible."

Replying to further questions, Major TRYON said that the Committee had already started work. One of the patients was undoubtedly very ill, but he understood that he was better. The other patients, including the orderly, were going on well.

Motor Accidents.

Mr. NOEL BUXTON asked the Secretary of State for the Home Department whether, having regard to the increase in the number of motor accidents in which young children lost their lives, he would consider the question of introducing further legislation with a view to increasing the penalties on negligent motorists.—Colonel W. ASHLEY (Parliamentary

Secretary to the Ministry of Transport) replied: No records are available which show separately the number of motor accidents in which young children have lost their lives. During the past few years the number of fatal road accidents in which motor vehicles have been involved has not shown any serious increase, taking into consideration the considerable increase in the number of motor vehicles on the road.

Reorganisation of Pensions Ministry and Ministry of Health.

Mr. FOOT asked the Secretary to the Treasury whether the reorganisation of the Ministry of Pensions had yet been completed, and, if so, what steps had been taken during regrading to put into operation Clause 2 of the Resolution of the House on August 5th, 1921, as to equality of opportunity for women; what branches of the Ministry previously closed to women had now been opened to them; whether women had now been excluded from any branch in which they were employed on August 5th, 1921; and what steps had been taken to ensure that women had an opportunity of training for the higher posts in the department irrespective of those posts which involved solely supervision of staff.—Major TRYON replied: The reorganisation of the Ministry of Pensions is not yet completed. Before regrading began the number of established posts held by women was very small, only 30 established women, excluding typists, being employed in the Department. Under the regrading scheme the number of posts above the rank of writing assistant allotted to women is 400. These posts are in five separate branches of the Ministry, as against six in which established women were employed before regrading. It has been found convenient to concentrate the greater part of the female staff in branches where the work is regarded as specially suitable to women. The opportunities given to women officers to train for higher duties are similar to those given to men of corresponding rank.

Mr. FOOT asked the Secretary to the Treasury whether the reorganisation of the Ministry of Health had yet been completed, if so, what steps had been taken during regrading to put into operation Clause 2 of the Resolution of the House on August 5th, 1921, as to equality of opportunity for women; what branches of the Ministry previously closed to women had now been opened to them; whether women had now been excluded from any branch in which they were employed on August 5th, 1921; and what steps had been taken to ensure that women had an opportunity of training for the higher posts in the department irrespective of those posts which involved solely supervision of staff.—Mr. NEVILLE CHAMBERLAIN replied: The rearrangements under the National Whitley Council's Reorganisation Report have been practically completed in the Ministry of Health. In the reorganisation full weight has been given to Clause 2 of the Resolution of the House of August 5th, 1921. Women have been promoted into all of the grades dealt with under the reorganisation scheme, including new posts in the administrative and executive grades. Women have not been excluded from any branch in which they were employed on August 5th, 1921. By placing women in the clerical, executive, and administrative grades full opportunity will arise of training for the higher posts in the Ministry.

MONDAY, JUNE 25TH.

Small-pox at Gloucester.

Mr. LEACH asked the Minister of Health what was the evidence that the epidemic which had occurred in the city of Gloucester was really an epidemic of small-pox, seeing that, although it was estimated that 2000 cases of the disorder had occurred, there had been a complete absence of invalidity or injury during the attack, an absence of any invalidity subsequent to the attack, and that the mortality had been nil; and could he explain why, under these circumstances, it was necessary for the Ministry to interfere or to issue his directions to deal with an outbreak which was associated with no untoward results of any description.—Mr. NEVILLE CHAMBERLAIN replied: The epidemic in Gloucester has been recognised as small-pox by a large number of local medical men, by officers of my department, and by Dr. C. Cameron, of the Metropolitan Asylums Board, who was called in as an expert by the Corporation. I may add that a number of cases of small-pox were recognised in other districts and traced to Gloucester. The statements in the question as to the absence of injury or invalidity either during or subsequent to the attacks are not correct, as I am informed that although the type of the disease is mild and no deaths have yet occurred many of the patients have been seriously ill. The action of my department has led to the localisation and control of an outbreak which had already begun to spread to other parts of the country and which, if unchecked, might have caused widespread disturbance of trade as well as danger to the public health.

TUESDAY, JUNE 26TH.

Small-pox at Gloucester.

Colonel Sir ARTHUR HOLBROOK asked the Minister of Health whether, having regard to the serious outbreak of

small-pox at Gloucester and elsewhere, he would consider the repeal of Section 1 (1) of the Vaccination Act, 1907, exempting persons conscientiously believing that vaccination would be prejudicial to the health of the child.—Lord E. PERCY replied: My right hon. friend cannot undertake to introduce legislation for the amendment of the Vaccination Acts during the present session.

Vaccination in the Army.

Mr. SNOWDEN asked the Under-Secretary of State for War how many vaccinations or re-vaccinations, per 1000 strength, were performed on British soldiers during each of the years 1914 to 1921, inclusive.—Lieut.-Colonel GUINNESS replied: The ratio per 1000 strength in 1921 was 250.10, but I regret that similar information for the earlier years is not available.

Small-pox in Germany.

Mr. BROMFIELD asked the Minister of Health whether he could state the number of cases of small-pox and the deaths from that disease which had occurred in Germany in each of the years 1917, 1918, 1919, 1920, 1921, and 1922.—Mr. NEVILLE CHAMBERLAIN replied: The following statement gives the number of cases of small-pox and the number of deaths from that disease which have occurred in Germany during each of the years in question. The figures for 1919 to 1922 are provisional and the numbers of deaths in 1921 and 1922 are not yet available:—

1917 ..	3043		456	1920 ..	2042		332
1918 ..	417		58	1921 ..	688		—
1919 ..	4431		704	1922 ..	215		—

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Thursday, July 5th.

ANNUAL GENERAL MEETING: at 5 P.M.

Business:

(1) To receive

- (a) the Report of the Council;
- (b) the Report of the Hon. Treasurers;
- (c) the Report of the Hon. Librarians.

(2) To elect the Officers and Council for the session 1923-24: to be immediately followed by a

SPECIAL GENERAL MEETING OF FELLOWS.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE POST-GRADUATE LECTURES, 1, Wimpole-street, W.

WEDNESDAY, July 4th.—5.30 P.M., Mr. Harold Chapple: Common Painful Gynaecological Conditions.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, July 2nd.—10 A.M., Mr. Maingot: Surgical Pathology. 2 P.M., Mr. Addison: Surgical Wards. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10.30 A.M., Dr. Paterson: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 11 A.M., Mr. Simson: Gynaecological Demonstration. 2 P.M., Dr. Burnford: Medical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Bishop Harman: Eye Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Banks-Davis: Nose, Throat, and Ear.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Nose, Throat, and Ear. 9.30 A.M., Dr. Burnford: Bacterial Therapy.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham, S.W.

WEDNESDAY, July 4th.—4.30 P.M., Dr. C. E. Lakin: Demonstration of Medical Cases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Demonstration of Clinical Cases at 3.30 P.M.

MONDAY, July 2nd.—Mr. Aubrey Goodwin: Gynaecological.

TUESDAY.—Dr. J. Metcalfe: Radiological.

WEDNESDAY.—Mr. C. H. Hayton: Throat and Nose.

THURSDAY.—Dr. Yealland: Medical.

FRIDAY.—Mr. E. Gillespie: Surgical.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

WEDNESDAY, July 4th.—4.15 P.M., Dr. W. M. Feldman: The Physiology of the Infant.

FRIDAY.—4.15 P.M., Mr. H. S. Souttar: Intracranial Tumours.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, July 5th.—4 P.M., Dr. Still: Convulsions: Their Significance and Treatment.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, July 5th.—5 P.M., Mr. T. B. Davies: Acute Abdominal Pain in Pregnancy.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.
MONDAY, July 2nd.—At Hereford, Mr. H. Chitty: Treatment of Painful Feet.

Appointments.

BROUGH, AGNES G., M.B., Ch.B. Edin., has been appointed Surgeon to the Ear and Throat Section of the Birmingham Hospital.

COHEN, E., M.R.C.S., L.R.C.P. Lond., House Surgeon, Princess Alice Hospital, Eastbourne.

FORREST, A. W., M.D. Edin., D.P.H., Deputy Medical Officer of Health and Tuberculosis Officer for the Metropolitan Borough of Wandsworth.

LESLIE, W., M.B., Ch.B. Lond., Resident Medical Officer, Worcester General Infirmary.

ROE, G. C. F., L.R.C.P. & S. Irel., D.P.H., Deputy Medical Officer of Health, Wakefield.

University of London: FOULERTON, A. G. R., F.R.C.S. Eng., Examiner for the Degree of M.D. State Med.; and SAVAGE, W. G., M.D., B.Sc. Lond., External Examiner in Hygiene and Bacteriology for B.Sc. Degree and the Diploma in Household Science.

Vacancies.

For further information refer to the advertisement columns.

Barbados General Hospital.—Jun. Res. S. £250.

Barnstaple, North Devon Infirmary.—H.S. £170.

Belfast, Queen's University.—Lecturer in Pharmacology. £450.

Belgrave Hospital for Children, Clapham-road, S.W.—Hon. Radiologist. 50 guineas.

Birmingham and Midland Hospital for Skin and Urinary Diseases, John Bright-street, Birmingham.—Asst. Radiologist.

Birmingham, Moryhull Colony for Epileptics, &c.—Asst. Res. M.O. £400.

Bristol Dispensary.—Non-Res. M.O.

Bromley Borough.—Asst. M.O.H. £500.

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Gt. Barrow, near Chester.—Med. Supt. £800.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250.

Colchester, Essex County Hospital.—Asst. H.S. and Reg. £150.

East African Medical Service.—M.O. £600.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Part-time Pathologist. £400.

Gloucester County Mental Hospital.—Locum Tenens. £7 7s. weekly.

Halstead and Belchamp United Sanitary Districts.—M.O.H., &c. £700.

Hospital for Women, Soho-square, W.—Hon. Asst. Anaesthetist.

Infants Hospital, Vincent-square, Westminster.—Pathologist.

London County Mental Hospital Service.—Seventh Asst. M.O. £440.

London Jewish Hospital, Stepney Green, E.—Hon. Asst. Anaesth.

Macclesfield General Infirmary.—Second H.S. £150.

Manchester, Ancoats Hospital.—H.S. £100.

Manchester, County Mental Hospital, Prestwich.—Locum Tenens. £8 8s. per week.

Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—Non-Res. H.S. £150.

Miller General Hospital for South-East London, Greenwich-road, S.E.—H.P. £150.

Oldham Royal Infirmary.—H.S.'s. Each £200.

Perth Royal Infirmary.—Res. M.O. £150.

Plymouth, South Devon and East Cornwall Hospital.—H.P. £100.

Queen Mary's Hospital for the East End, E.—Cas. O. £150. Also Hon. M.O. for Radio-Electro-Therapeutic Dept.

Reading, Royal Berkshire Hospital.—Hon. P.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P.

Royal Naval Medical Service.—Surgeon-Lieutenants.

St. Bartholomew's Medical College.—Demonstrator of Biology.

Salford Royal Hospital.—Hon. Dental S.

Salford Union Infirmary, Hope, Pendleton, near Manchester.—Third and Fourth Asst. Res. M.O.'s. Each £200.

Shrewsbury, Royal Salop Infirmary.—H.P. £160.

Southampton County Borough.—Asst. M.O.H. £500.

South London Hospital for Women, Clapham Common, S.W.—Clin. Asst. £1 1s. per attendance.

South Shields, Ingham Infirmary.—Jun. H.S. £150.

Sunderland Royal Infirmary.—H.S. £160.

Tunbridge Wells General Hospital.—H.S. £160.

Wandsworth Metropolitan Borough.—Locum Tenens. 10 guineas weekly.

West African Medical Service.—M.O. £660.

Western Dispensary, 38, Rochester Row, S.W.—M.O.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Alton, Staffs; Epsom, Surrey.

Births, Marriages, and Deaths.

BIRTHS.

GWYNNE-JONES.—On June 18th, at The Little House, Gerrards Cross, Bucks, the wife of Dr. H. Gwynne-Jones, of a son.

HALSTEAD.—On June 20th, at Russell Hill, Purley, the wife of Dr. Oliver Halstead, of a daughter.

MAHON.—On June 19th, at Upper Brook-street, Grosvenor-square, the wife of Dr. Edward M. Mahon, of a daughter.

DEATHS.

EMERY.—On June 19th, at Red Cross Hospital, Brighton.

Walter d'Este Emery, M.D., M.R.C.P. Lond., aged 53 years.

GIRVIN.—On June 25th, at a nursing home, Colonel John Girvin, (A.M.S. retired), aged 61 years.

LAMB.—On June 19th, at The Orchard, Marlow, William Henry Lamb, M.B., aged 72.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

SOCIETY FOR PRESERVING THE HEALTH OF THE JEWS.—Some statistics of the sanitary conditions among the Jews in Russia and an account of the activities of the O.Z.E. (Society for Preserving the Health of the Jews) were given by Dr. M. Schwartzman at a meeting of Jewish doctors at Jews' College, Bloomsbury, on June 10th. He said that the civil war and the social revolution had resulted in complete economic ruin, in which the Jews were the principal sufferers. The rate of mortality was computed at 80 per 1000, and in some places it reached 150–200 per 1000. The rate of births sharply declined, and the power of resistance was greatly lowered. Dr. Schwartzman's address had for its object the stimulation of interest in the O.Z.E. organisation. Started before the war with the object of stemming the effects of economic and political persecution on the physique of the Jewish masses, the O.Z.E. had established before the revolution a network of institutions, hospitals, sanatoria, open-air colonies, and the like, and had developed physical culture and sanitary education with marked results. Between 1914 and 1918 the O.Z.E. had got to work in 218 localities, with 105 hospitals and 190 sanitary establishments, and was taking care of 90,000 children. The budget of the O.Z.E. in these three years exceeded £500,000. A resolution was passed to establish in London an organisation in support of the O.Z.E. Dr. Redcliffe N. Salaman, who presided at the meeting, read out a number of messages containing expression of support and sympathy, among them letters from Lord Robert Cecil, Mr. Ramsay MacDonald, Sir Sydney Russell-Wells, Sir Frederick Mott, Dr. Charles Myers, and Prof. Zeligman. Mr. A. H. Levy, F.R.C.S., was elected chairman of the committee which will be in charge of the work of the organisation.

Notes, Comments, and Abstracts.

THE ANATOMY OF THE DRIVING GRIP IN GOLF.

BY WM. CUTHBERT MORTON, C.B.E., M.D. EDIN.,
HONORARY DEMONSTRATOR IN ANATOMY, UNIVERSITY OF LEEDS.

To understand the driving grip in golf, we must consider, first, the object to be gripped, which is the club known as the driver, and, secondly, the gripper, which is the hand. Although both hands are used it will be enough to study the mechanism of one, preferably the right.

The Driver.

The driver is simply a shaft of wood leathered at its near end to form a handle, and at its far end fitted laterally and obliquely with a head, which, when the handle is obliquely gripped, and the whole club obliquely swung, should sweep the ground and propel the ball without rotating the shaft, and so giving a wrong direction to the "stroke." Before the stroke the club must be swung, and before the swing the ball must be "addressed," the whole body being adjusted in preparation for the swing. The club must be so gripped that the grip may be maintained throughout and after the swing, keeping the club all the time under control, yet all the time allowing it the fullest possible freedom. To understand the grip we must see the hand working in coöperation with the forearm.

The Hand.

Each hand is made up of the "palm" (metacarpal part of the hand) and the digits. The palm as seen from in front consists of the ball of the thumb, the ball of the little finger, and the somewhat triangular part which is bounded at the sides by these and below at its base by the webs and the first creases of the index, ring, and middle fingers, the apex of the triangle being above towards the wrist. The palm includes the wrist-bones, with which we are not here concerned. It has also five metacarpal bones, one for each digit, the four for the fingers being relatively immobile, while that for the thumb is more free. The digits are jointed to the palm, and they are also jointed within themselves in such a way that each finger has three separate parts (phalanges) and the thumb has two. The phalanges are numbered in order from the palm to the finger-tips.

The Fingers.

When the hand lies on its back at rest, all the phalanges of the fingers are slightly flexed (bent forwards) in such a way as to form an almost transverse groove, the bottom of which corresponds to the creases between the first and second phalanges. The groove is deeper opposite the middle and ring than opposite the index and little fingers, and it is also unclosed above towards the wrist. A club laid in this groove rests primarily on the index and little fingers. The club may now be gripped by further flexing the second and third phalanges of all the fingers round it, and while this is being done the first phalanges may either remain flexed or else be fully extended (kept in line with the palm). If the club be gripped with the first phalanges flexed, it will be found that if at the same time the wrist be progressively flexed the grip gradually weakens, especially for the index. This weakness is due to the passive pull of the extensor muscles, the tendons of which come from the forearm and arm, and are so short that when the wrist is fully flexed they obtain slack by extending the first phalanges, and especially that of the index. Whenever the wrist must be fully flexed, the first phalanges of the fingers cannot be much flexed, and least of all that of the index. On the other hand, so long as the first phalanges are not flexed, the grip retains its power, even if the wrist be fully flexed. In tennis this of itself determines the form of many a stroke. In driving a golf ball the wrist should never be flexed in the swing, but at the end of the backward and beginning of the forward swing it must be well extended and abducted, and the description just given of the weakening of the grip in flexion of the wrist because of the passive pull of the extensors enables us to understand the less obvious weakening of the active hold of the long flexors of the fingers during strong extension and abduction, or, on the other hand, the limitation of extension and abduction of the wrist if the fingers be fully flexed.

The finger-grip just described is transverse, and so is ill adapted to the obliquity of the club. The hand can be made somewhat oblique by adduction of the wrist, but this is not enough. It has just been seen that if the first phalanx

of the index be extended it does not matter so much about those of the other fingers; it is enough if the club be securely gripped at the entry to the groove. We may therefore range the fingers with the index lowest (its first phalanx being extended) and the little finger highest (its first phalanx being flexed), in this way securing an oblique finger groove which, though open above, is well adapted to the obliquity of the club at the moment of impact.

The Palm.

In passing we may note that there is also a palm-grip, in which the club is laid across the "palm" of the hand and the fingers all close round it. This is more powerful than the finger-grip, but in golf, in which the ideal is sufficient range and suppleness without unnecessary force, this palm-grip has several drawbacks, since (a) the line of the fingers is not sufficiently oblique, (b) the phalanges have not so close a hold on the club, and (c) this hold is unstable if the wrist be well extended and abducted.

Apart from the thumb, then, the ideal is the oblique finger-grip described above, in which the club lies in a groove bounded at its entry by the three phalanges of the index and at its exit by the three phalanges, and more or less also by the ball of the little finger. With this grip (a) the fingers are adjusted to the obliquity of the club, (b) by elongating the groove the fingers gain in control of the club, (c) the encircling hold of each finger on the club is at its best, (d) the grip can be maintained in every posture of the wrist.

The Thumb.

We must now consider how this groove is closed in above and so converted into a tunnel by the thumb. The latter consists of two parts, the ball of the thumb and the thumb proper. The ball of the thumb is its "palm" part, while the thumb proper consists of the two phalanges. In studying the movements of the thumb it is well to have a neutral posture from which we may start, and for our present purpose we may begin with the posture of the thumb when the hand lies on its back at rest, in which case the thumb lies at some distance in front of the rest of the hand and points down and outwards from the wrist, the first phalanx being slightly flexed and slightly adducted (slightly bent towards its palm and slightly towards its inner side) and the second rather more flexed. Retaining the metacarpal in this posture we may now extend the two phalanges and so get the neutral position of the thumb. From this neutral position the metacarpal may be moved in two main planes and slightly also around its own long axis. The first plane bisects the back (nail to wrist) and also the palm of the thumb, and in this plane the whole thumb may be flexed and extended. The second plane is at right angles to the first, passing through the borders of the nail, and in this plane the thumb may be adducted and abducted (metacarpal and first phalanx). Lastly, the thumb (metacarpal and first phalanx) may be slightly rotated on a long axis so that its palmar aspect moves slightly towards either side. *Extension* (with abduction) is well seen in making as big a span as possible between the tip of the thumb and that of the little finger, *flexion* (with abduction and inward rotation) in opposing the thumb and the little finger, that is, in making the tips of these digits meet palm to palm, *abduction* (with extension and inward rotation) in parting the thumb and index in order to encircle a wide drinking vessel, *adduction* (with some flexion) in laying the thumb in line with and in front of the index, *rotation* (with other movements) in changing (a) from the flattened hand (in which posture the palm of the second phalanx of the thumb rests against the outer face of the first phalanx of the index, and the nail can scarcely be seen from the front) to full opposition with the little finger (in which posture the whole nail may be visible), (b) vice versa.

The Grip.

We are here concerned mainly with flexion, adduction, and abduction,† and it should be noted that these two sideward movements are relatively weak, whereas the palmward movement of flexion is strong. This has an important bearing on the thumb-grip. If the club be first gripped by the fingers as already described (oblique finger-grip), the thumb must take up one of the three main positions: (1) It may ride with the whole length of its palmar aspect applied to the club and its tip pointing downwards towards the head. (2) It may lie to its own side of the club with the palm of its two phalanges applied to the outer side and back of the index, and its outer side pressing on the club. (3) It may cross over the club and lie either with its palm on the outer border of the index and its inner border pressing on the club or else with its palm and inner border pressing on the back of the index and middle finger. In (2) the grip is unstable because the tunnel is closed only by the ball of the thumb, and at its entry the side pressure of the thumb is weak, and the openness of the tunnel allows too free movement towards the interval between the tip of the index and the

* In this paper the word *palm* is used in two senses, (1) the hand without the fingers; (2) the grasping side of the hand. Though unscientific, this cannot be avoided, without coining a new word, which I should be very loth to do.

† Note the important part played in abduction by the tensor of the palmar fascia (long palmaris).

ball of the thumb. In (3) the grip is more stable in that more use is made of the long flexor of the thumb, but the entry of the tunnel allows too free movement towards the web of the thumb and index, and again the wrist cannot be fully extended and abducted unless the long flexors of the fingers (which from this position act also as adductors of the wrist) are partially relaxed and so lose hold on the club. In (1), the grip is ideal because (a) the tunnel being prolonged the leverage is better and the club can be controlled with less effort; (b) the entry of the tunnel is closed (or at least, pressure is applied to the club) on three sides by the three phalanges of the index and on the fourth by the thumb; (c) the grip can be maintained in every position of the wrist without the fingers weakening their hold; (d) a certain degree of variation in the obliquity of the tunnel is left to the choice of the golfer, according to the type of his hand, or his personal preference, since, while the entry to the tunnel will vary little, its exit may be widened so that the club may lie either parallel to and in contact with the whole thumb and at some distance from the first phalanx of the little finger, or else in closer association with the little finger at some distance from the ball of the thumb at the exit of the tunnel.

The oblique finger-grip with riding thumb is the one which has been empirically evolved as the ideal. This empirical choice would appear to be justified on anatomical grounds.

Finger-grip v. Palm-grip.

The flexors and extensors of the hand modify its activities not only by means of voluntary contraction and relaxation, but also by their reflex tone. No muscle can act except within the limits imposed by (a) the lengthening and shortening of its belly, (b) the length and elasticity of its tendon. Differences in the correlation of these factors give rise to remarkable differences in the function of this part of the limb.

(a) With the arm hanging at the side it is impossible to support an unattached weight by the long flexors of the fingers without voluntary effort, but if the elbow be now flexed until the forearm is horizontal and the hand at rest on its back (the wrist being extended by the weight of the hand), the resting tension of the long flexors will keep the fingers so flexed that in this posture they will support some little weight (e.g., on the second phalanges) without being fully extended, and if the weight be sufficiently increased the fingers will become extended and the wrist will become flexed.

(b) In certain animals which live for the most part in trees, such is the hold of the long flexors on the phalanges that the whole body can be slung from a bough with little or no voluntary effort.

(c) Very young babies have a strong enough finger-grip to support the whole body for a few seconds. They have not yet developed the power of the thumb.

(d) In adults (in whom the power of the thumb has become fully developed) there is a distinct difference in the function of the finger-grip and that of the palm-grip. For a pull in one direction only (e.g., in stretcher-bearing or in boarding a moving tram-car) the finger-grip may be more useful, especially if the strain is prolonged and not otherwise too severe. On the other hand, when the immediate strain is very great, or, if the direction of the opposing force is liable to vary, the palm-grip with encircling thumb may be needed.

MIDWIFERY IN UGANDA.

WE have received a copy of a manual of midwifery written in Luganda—the language of the Baganda, the people of the Uganda Protectorate—by Dr. Albert R. Cook, senior physician, C.M.S., Mengo Hospital, Kampala, and Mrs. Cook, superintendent of the Maternity Training School, Namirembe. In an English preface the authors explain that since the rise of educational institutions in Uganda the need has become urgent for books written in the language of the people; the Baganda are described as having an extraordinary aptitude for learning, and the purpose of the book is to give an initial start in midwifery. The needs of Uganda in this connexion are sufficiently serious. From 17-20 per cent. of the natives are suffering from active venereal disease, and about 80 per cent. have at one time or another during their lives contracted syphilis. The Baganda are a fine race—Sir Harry Johnston has described them as “the Japanese of Central Africa”—and the threatened depopulation of their country is a thing to be averted. Statistics kept at Mango Hospital for more than 20 years show the following facts:—

(1) Two out of every three Baganda mothers have had syphilis—practically 66 per cent. (The rate for large towns in England has been put at men, 10 per cent., women, 5 per cent.)

(2) The ante-natal mortality is 67 per cent. in pregnant women suffering from syphilis.

(3) The deaths under 12 months old in Uganda are 330 per 1000 births (in England, 80 per 1000).

(4) Of every 100 conceptions in Baganda women, only 45 survive to the end of the first 12 months.

(5) Treatment in hospital, such as trained native midwives would easily be enabled to give, has already reduced this high mortality by three-quarters at different centres in the Protectorate.

(6) Given adequate support, in ten years' time a proper supply of trained native midwives should change a diminishing population to an increasing one.

Dr. and Mrs. Cook have worked in the Church Missionary Society's Hospital at Namirembe for 26 years, during which time they have always given simple teaching in midwifery, but definitely organised training was only begun in 1919, when a large maternity training school was opened; three contingents of trained midwives have already passed out and are doing useful work.

HEALTH CONDITIONS ON THE GOLD COAST.

AT the census taken in 1921 the population of the Gold Coast and dependencies was 2,078,043—an increase of half a million on the population in 1911. Europeans resident in the colony during 1921 comprised 768 officials, 1556 mercantile, 541 mining, and 74 missionary—total 2939. In the same year the number of births registered in the 16 registration areas were: European, 1; natives, 2962. And of deaths: Europeans, 32; natives, 2884. Although there was an increase in the population the number of deaths showed a decrease of 689—attributed to improved sanitary conditions in the larger towns. Pulmonary and intestinal diseases were the principal causes of death. The death-rate amongst Europeans was 10.88, and the invaliding rate 30.76 per 1000. During the year 2821 Europeans and 54,621 Africans were treated in the hospitals and dispensaries of the colony, as compared with 2898 and 55,687 respectively in the previous year. Treatment was given in 5946 cases of malaria, 710 of dysentery, 4 of yellow fever, 370 of pneumonia, 337 of tuberculosis, and 8 of sleeping sickness. Of 21 cases of blackwater fever treated 9 proved fatal, and 3 of the 4 cases of yellow fever resulted in death; 87,449 vaccinations were performed during the year, of which 58,073 were verified as successful. The rainfall varies with the configuration of the country; in 1921 it ranged from 34.43 inches at Accra to 88.13 inches at Axim. At Accra the mean shade temperature for the year was 79.84° F., at Coomassie 80.11°, and at Secondee 81.46°. The climate, though hot and damp, is cooler than that of most tropical countries situated in the same latitude. It is not in itself unhealthy, but an evil reputation has been earned for it in the past by the prevalence of mosquito-borne diseases, against which all possible precautions have constantly to be taken. The Gold Coast is peculiarly free from many of the discomforts associated with tropical countries; hot nights and intense heat by day are the exception rather than the rule, while insects are comparatively unobtrusive. The efforts of the medical and sanitary authorities in promoting the treatment of disease and the knowledge of general hygiene continue to exercise a beneficial effect on the general health of Europeans.

INSTRUCTION IN MOTHERCRAFT.

A SHEAF of 24 “Mothercraft Posters” has been brought out by Miss M. Olive Haydon (John Bale, Sons and Danielsson, Ltd. 7s. 6d.). These posters, printed in two colours in bold lettering for use in welfare centres, are arranged in calendar form on a wooden roller, each page containing a few short, simple rules on various aspects of child management, including character-formation, breast-feeding, sleep, clothing, diet, management of bowels, crying, colds, and vaccination. The advice given is uniformly good.—Two series of four-page leaflets entitled “Talks to Mothers,” by Sister Lily Skene (same publisher, 2d. each) are appearing in monthly instalments, one dealing with infant care, the other with character-training. The talks, while devoid of any pretensions to literary style, are simple and practical.

A NEW VERSION OF THE COUVADE.

A CORRESPONDENT sends this story: “There is a family here where a baby was expected, and according to custom, about a week before the calculated arrival, the two other children of the family, aged 7 and 5 respectively, were sent away to an aunt. In due course a telegram arrived saying, ‘Girl born such and such a date.’ So the aunt told the children that they had a new little sister, and said, ‘I expect you would rather have had a little brother.’ Whereupon the 7-year old child said, ‘Oh, that’s all right, we shall have one soon.’ The aunt, naturally curious about this prescience, asked why she was so sure. ‘Well, aunty,’ she said, ‘before this baby came mummy used to lie on the sofa nearly all day, but three days before we came here father took to lying on the sofa too. He said it was gout, but we knew better.’”

RECENTLY ISSUED **Ewing's Neoplastic Diseases** NEW (2nd) EDITION

"Professor Ewing has produced a book which will, we think, be recognised as the standard work of reference on this subject in the English language for many years to come. His knowledge of the Literature is immense, and he has drawn upon it freely, so that, although the book is based on his own experience, practically every page contains reference to the work of others. It is remarkable that such a stamp of individuality should have been retained in so broad and catholic a survey of the subject. . . . We cordially congratulate Professor Ewing on the success which has attended his labours."—THE LANCET.

Neoplastic Diseases. By JAMES EWING, Sc.D., M.D., Professor of Pathology, Cornell University Medical School. Octavo of 1050 pages, with 512 illustrations. Cloth, 55s. net.

W. B. Saunders Company, Ltd., 9, Henrietta Street, London, W.C.2.

Valentine's Meat-Juice

In Diarrhoea, Dysentery and Cholera Infantum where it is Essential to Conserve the Weakened Vital Forces without Irritating the Digestive Organs, Valentine's Meat-Juice demonstrates its Ease of Assimilation and Power to Sustain and Strengthen.

W. B. Scranton, M.D., Medical Superintendent, Korean Mission Methodist Episcopal Church, Seoul, Korea: "A most excellent use I frequently put VALENTINE'S MEAT-JUICE to is tiding Babies through Cholera Morbus and the Wasting Diseases incident to Summer and Inanition. It acts at once, and many a crisis has been passed safely by my patients, through the agency of VALENTINE'S MEAT-JUICE. It has also been of great value in my practice in the Far East in the treatment of that form of Summer Diarrhoea known as Sprue, where it tides the patients over until they can get to a better climate."

F. E. Gordon, M.D., Anniston, Alabama: "My baby took VALENTINE'S MEAT-JUICE with relish and with great benefit, and to its sustaining properties I think her recovery from one of the worst cases of Entero-Colitis I ever saw was largely due."

For Sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
RICHMOND, VIRGINIA, U. S. A.

VACCINE TREATMENT FOR TUBERCULOSIS

Detoxicated Tubercle Bacillus Vaccine is prepared from virulent strains of Tubercle Bacilli. The germs are subjected to mechanical disintegration in the presence of weak alkali which acts as a solvent to the liberated bacterial protoplasm. The waxy or "fatty" portion, forming an insoluble residue, is completely separated by filtration through Berkefeld filters, and is discarded, consequently this preparation is a

"DEFATTED" VACCINE

as well as a Detoxicated Vaccine.

A large quantity of this vaccine is now available.

HALITOSIS

(AS DEFINED IN THE CENTURY DICTIONARY)

(Hal-i-to-sis) N. N. L.

(L. Halitus—Breath :: Osis—Offensive)

Offensive breath, whether arising from diseased or neglected conditions of the teeth, mouth or nose or caused by disorders of digestion, respiration, the excessive use of tobacco, etc., may be readily overcome by the deodorizing properties of—

LISTERINE

Listerine is strictly antizymotic, it inhibits alike the acid fermentation of carbohydrates and the alkaline putrefactive processes of mixtures of meat and saliva, retained as debris about the teeth; hence, Listerine is antagonistic to the activating enzymes of fermentation so often the cause of Halitosis.

The volatile antiseptic constituents of Listerine—thyme, eucalyptus, gaultheria and mentha, combined with baptisia, boric acid, rectified spirits and water have a stimulating effect upon the stomach and in proportion to the dose, an action inhibitive to fermentation of its contents; hence, Listerine is often corrective of those disorders associated with the endo-development of gases and acid eructations. A large tablespoon of Listerine in a wine glass of hot water will afford immediate relief.

Intestinal Disinfection

No. 10. BACILLUS COLI, BACILLURIA AND URINARY INFECTIONS

Conditions dependent upon infection of the urinary tract by *B. coli* are by no means uncommon and present varying degrees of severity from serious suppurative lesions of the kidney to mild bacilluria of little importance.

The mechanism of infection by *B. coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B. coli* are common in urinary infections in the male).

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed and those already located in the urinary tract may be attacked by a urinary antiseptic. By the combined administration of KEROL, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B. coli* is placed on a rational basis, and many cases are cured by this line of treatment when they fail to yield to urotropin alone.

For intestinal disinfection use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

KEROL CAPSULES

An infant food of proved value

For more than forty years M.O.F. has been used with the greatest success, both as an infant food and as a nourishing diet for invalids and the aged.

It is a *natural* food, with a higher percentage of proteid matter and fat than any similar preparation; easily digestible, though not pre-digested; and zanthin free.

M.O.F. is generally successful with weakly infants when all other foods have failed.

A testing sample of M.O.F. will be sent post free to any Doctor or Nurse on receipt of card.

Fandorine

for

Menstrual Disorders.

Prepared at CHATELAIN'S LABORATORIES, PARIS.

Active Principles

Ovarian and mammary extracts.
Anemone pulsatilla.
Piscidia erythrina.
Viburnum prunifolium.

Indications

Uterine hæmorrhage, Fibromas,
Puberty, Irregular or painful
menstruation, Menopause.

Fandorine is an association of the substances of the two essential types of the genital glands, to which are added the active principles of anemone, and constitutes a specific for all diseases peculiar to women. It *regulates the functions*, arrests hæmorrhage and suppresses painful symptoms.

Fandorine should be taken by any woman who suffers from irregularities or painful symptoms. It is highly recommended for young girls at the period of formation, as well as for women at the critical age.

Fandorine is also highly recommended during the period of pregnancy and nursing.

Necessary quantity for Clinical Trial obtainable post free from

NECESSARY IN DIVERTICULITIS

A specialist of international reputation, after defining Diverticulitis as the formation of small pouches along the walls of the colon due to prolonged constipated conditions, points out that these pouches, becoming filled with faecal matter, quickly cause inflammation which leads to ulcers of the bowel, abscesses or adhesions—even the growth of tumor masses and obstructions. A very serious condition, which, he says, is to be remedied only by careful non-constipating diet and the administration of paraffinum liquidum.

NUJOL is the ideal paraffinum liquidum for the correction of intestinal disorders. Its purity, quality, and general suitability to conditions of intestinal stasis are attested by leaders in the medical profession.

In determining a viscosity best adapted to general requirements, the makers of Nujol tried consis-

tencies ranging from a water-like fluid to a jelly. The viscosity of Nujol was fixed upon after exhaustive clinical test and research and is in accord with the highest medical opinion.

Sample and authoritative literature dealing with the general and special uses of Nujol will be sent gratis. See coupon below.

L

Invalid Bovo-Lactin

in the treatment of acute illness

INCIDIT in Scyllam qui vult vitare Charybdim" aptly illustrates the position of the physician in his endeavours to steer a case through an acute illness.

He has to avoid on the one hand the dangers attending a diet which however nourishing it may be in the ordinary way, is utterly unsuitable for the weakened assimilative powers of his patient, and on the other hand, the equal danger of not ordering a sufficiency of food to replace the wasted tissues and increase bodily resistance to the processes of disease.

INVALID BOVO-LACTIN

forms the ideal dietary in acute illness.
It possesses every requirement.

It is concentrated.

It possesses a very high protein content.

It can be assimilated by the weakest digestive organs.

It is very agreeable and produces no dis-taste.

It has marked revivifying powers.

(For analysis see "British Medical Journal," June 9th, 1923, page 13 of advertisements).

A teaspoonful may be given every three hours or oftener, either alone or in milk, brandy or wine.

Other preparations of BOVO-LACTIN are:—

Bovo-Lactin Essence for tired workers, convalescents, growing children.

Bovo-Lactin Chocolate — a perfect food in health and sickness.

Bovo-Lactin Gruel—specially valuable for nursing and expectant mothers.

These preparations are manufactured under the strictest scientific control. Special attention is devoted to the hygienic conditions of the Works. Daily chemical and bacteriological examinations are made by a specially trained staff to ensure absolute purity.

When Metabolism is Faulty

OVALTINE

TONIC FOOD BEVERAGE

Easily Digested, Readily Assimilated, Palatable,
Soluble, Highly Nutritive, Essential Food
Elements in Correct Ratio. Reasonable in Cost.

The above are the distinguishing features of this delicious combination of ripe barley malt, creamy milk, fresh eggs and the purest cocoa. A complete food, that reinforces the diet in a way necessary to ensure successful treatment.

A deservedly popular prescription in the dietetic treatment of tuberculosis, chlorosis, gastric or duodenal ulcer, nervous disorders, infantile marasmus, and convalescence after fever or operation. In agalactia 'Ovaltine' is a definite galactagogue.

A. WANDER Ltd., 45, Cowcross Street, London, E.C. 1.

Works: KING'S LANGLEY, HERTS.

Drawing of a wall painting in a Theban Tomb, depicting Egyptian ladies at a feast.

A liberal supply of 'Ovaltine' sent free to medical men in private or hospital practice.

Cocaine is no longer needed
Use **BUTYN**—the safe substitute for Cocaine

BUTYN IS FAR SUPERIOR TO COCAINE AS A LOCAL ANÆSTHETIC

International action is being urged by the Medical Profession to abolish the manufacture of cocaine. Its use, according to authorities, is no longer necessary in medical or dental practice.

BUTYN, the new synthetic substitute for cocaine, has been tested widely and with very good results (see *British Medical Journal*, January 13th, and Communication to the *London Times* of March 24th by Sir W. M. Bayliss and Dr. C. W. Saleeby).

A report of the Research Committee of the Section of Ophthalmology of the American Medical Association, and other literature will be sent on request.

BUTYN IS SUPPLIED IN THE FOLLOWING FORMS:—

2% Solution, 1 oz. Bottles.

Butyn Tablets, grs. 3-10.

Butyn and Epinephrin Tablets, each tablet containing: Butyn gr. 1/6, and Epinephrin gr. 1/1250. Bottles of 100 tablets.

Butyn Powder, 5 grams.

BUTYN is now available in Great Britain from these and other distributors:—

STEELE & MARSH, 6, MILSOM STREET, BATH, ENGLAND.

ALLEN & HANBURYS, LTD., LONDON.

BRITISH DRUG HOUSES, LTD., LONDON.

WM. MARTINDALE, LONDON.

L. PORRO, LTD., LONDON.

SAVORY & MOORE, LTD., LONDON.

THE ABBOTT LABORATORIES, CHICAGO, U.S.A.

Canadian Office: 221, W. RICHMOND STREET, CANADA.

HE formula of ROBOLEINE indicates that this is a tonic unique and the strongest support is given to this assumption by the fact of

having been prescribed so widely for the past fifteen years.

THE FORMULA OF ROBOLEINE

Red Bone Marrow from the Long Bones of Oxen ; Jelly from the Rib Bones ; "Cream of Malt" ; Egg Yolk (Lecithin) ; Neutralized Lemon Juice.

CONSTITUENTS OF ROBOLEINE

Animal Fats, Maltose, Diastase, and natural nitrogenous and phosphoric compounds, together with the Vitamins "A," "B," and "C."

"THE LANCET" says: "By its palatability and general excellence 'Roboleine' has taken the high rank to which it is entitled among dietetic aids."

In all cases of mal-nutrition it has been found that ROBOLEINE is a most valuable ally, and in support of this one cogent fact may be quoted: practically all the child-welfare centres and children's sanatoria use it regularly.

Please write for Free Sample and Literature.

RATIONAL ORGANOOTHERAPY

THE DEPENDABLE PRODUCTS OF A BRITISH HOUSE.

*The Most Extensively Prescribed Organo-
therapeutical Products in Great Britain.*

LYMPH SERUM.

A pluriglandular product for hypodermic injection, the base of which is Spermin. Employed with great success in combating nervous disorders and in arresting, by compensation, organic degeneration. It has proved especially useful in the treatment of Locomotor Ataxia, Disseminated Sclerosis, Cerebral Degeneration, and Impotencia.

LYMPHOID COMPOUND.

A pluriglandular preparation with Spermin as its base and put up in soluble gelatine capsules. Widely prescribed, with exceptionally gratifying results, in Neurasthenia, Nervous and Mental Instability, Neuroses, Psychoses, Shock, Insomnia and in conditions resulting from glandular insufficiency, metabolic disorder, imperfect oxidation, impairment of nutrition, Fatigue and Exhaustion, and Impotencia.

OVAMAMMOID COMPOUND.

A product of great service, the professional demand for which (as in the case of the other products) is extensive and constant. Put up in soluble gelatine capsules, and having for its base Ovarian Extract and Mammary Gland Extract of maximum activity, it compensates for Ovarian Insufficiency, combats conditions resulting therefrom, secures normal menstrual functioning and controls the disturbances of the menopause.

OPOCAPS (Regd.).

(Soluble Gelatine Capsules).

- *PITUITARY EXTRACT.
Whole Gland.
Posterior Lobe. (Capsules or Injections.)
Anterior Lobe or
- *PITGLANDIN.
- *PARATHYROID EXTRACT.
- *THYROID EXTRACT.
- *THYMUS EXTRACT.
- *PROSTATIC EXTRACT.
- *ORCHITIC EXTRACT.
- *OVARIAN EXTRACT.
- *CORPORA LUTEA EXTRACT.
- *MAMMARY GLAND EXTRACT.
- *PLACENTA EXTRACT.
- *SPLENIC EXTRACT.
- *SUPRARENAL EXTRACT.
- *ADRENIN (B.O.C.)
- *HEPATIC EXTRACT.
- *RENAL EXTRACT.
- *PANCREATIC EXTRACT.
- PANCREATOKINASE.
- BILIARY EXTRACT.
- *GASTRIC MUCOSA EXTRACT.
- *LYMPHATIC GLAND EXTRACT.
- *RED BONE MARROW.
- *BRAIN EXTRACT.
- *SPINAL CORD EXTRACT.

or any Combination thereof.

Also supplied in ampoules for Hypodermic injection.

EUKINASE.

A scientifically prepared product containing the entire condensed duodenal juice in a dried state and in an active and unalterable form. It contains in a maximum degree of activity the digestive ferment Enterokinase and Secretin. This product is employed with gratifying results in the treatment of Duodenal Insufficiency and conditions arising therefrom. Constipation, Intestinal Indigestion, Pancreatic Insufficiency, Gastro-Intestinal Insufficiency, Infantile Diarrhoea and Fermentation, Diarrhoea of Adults, Steatorrhoea, Coprostasis, Dyspepsia, Flatulence, Nausea, Anorexia, Emaciation, and Glycosuria are conditions which have responded well to this product.

HYPOTHYROIDINE.

A trustworthy product employed successfully in the treatment of Exophthalmic Goitre. It is scientifically prepared from materials derived from the Serum (together with all the active principles extracted from the blood) of thyroidectomised horses.

EVATMINE FOR ASTHMA.

A dependable preparation supplied in ampoules for hypodermic injection, which contains, among its ingredients, Adrenin and Post-Pituitary Ext. It secures complete control in Asthmatical Paroxysms in five minutes or less, usually after one injection and produces no adverse reactions. Free supplies for testing if desired.

TYPICAL LETTERS OF APPRECIATION FROM BRITISH MEDICAL PRACTITIONERS READ AS FOLLOWS:—

LYMPHOID COMPOUND.

"I am more than satisfied with your Lymphoid Compound. I have now prescribed it in 90 cases of Neurasthenia. The product has proved invaluable in my cases of Neurasthenia, Fatigue and Exhaustion, and Nervous Instability. It has not failed in a single case."

—M.R.C.S., L.R.C.P. (Lond.)

OVAMAMMOID COMPOUND.

"I have obtained such remarkably good results by your Ovamammoid Compound in my cases of Climacteric Disturbance, Dysmenorrhoea, and Menopausal Obesity, that I always prescribe it for such cases."

—M.B., Ch.B. (Edin.).

EVATMINE.

"I have been treating a very intractable case of Asthma with your preparation 'Evatmine.' The patient had been a severe sufferer for years, and the case had refused to respond to any other method of treatment. The patient obtained instant relief and a good night's rest after the first injection. Two further injections gave the same excellent result. It is six months since she had the last injection, during which time she has not had a single attack of asthma. Such a result is indeed remarkable."—M.D., B.Ch. (Edin.).

SUPPLIED TO PRACTITIONERS OR ON THEIR PRESCRIPTIONS ONLY.

THE BRITISH ORGANOOTHERAPY CO., LTD., makes a speciality of meeting the constantly growing demand by Medical Practitioners for Pluriglandular products to their own formulæ (with or without the inclusion of Pharmacopœial adjuvants), for the treatment of special cases. These compounds are dispensed from FRESH MATERIALS, at short notice, and at reasonable rates.

Interesting literature, monographs in respect to any phase of Modern Organotherapeutics and authentic clinical data sent on request.

'BYNIN' Amara

"A Distinct Advance on Easton's Syrup."

—The 'Lancet.'

'Bynin' Amara is an analogue of the well-known Easton's Syrup, but it is therapeutically much superior to that preparation. The syrup is replaced by 'Bynin,' pure active Liquid Malt, which affords a far better vehicle than the former, as it is actively digestive and nutritive. An added advantage is that the nauseous flavour of Easton's Syrup is effectively masked, whilst there is no possibility of sugar crystallising out and carrying down with it the active alkaloidal principles.

DOSE FOR ADULTS—A dessertspoonful to ■
tablespoonful in twice the quantity of water twice
or on occasion three times daily.

*Further particulars and free sample will
be sent on request.*

EXAMPLES OF WORK DONE BY PIONEER AND MASTER ARTISTS IN THE ÆGEAN AREA.—The delight with which archæologists came upon the lost beginnings of Greek civilisation was perhaps never greater than when paintings by Ægean pioneers were revealed to their astonished gaze. The discovery of the beautiful masterpiece of fresco, known as the "Cupbearer," here reproduced on the right, was the first of these. "The colours were almost as brilliant as when laid down over three thousand years before. For the first time the portraiture of a man of this mysterious Mycenæan race rises before us. There was something very impressive in this vision of brilliant youth and of male beauty, recalled after so long an interval to our upper air from what had been till yesterday a forgotten world." The artist who painted this fine picture had not yet learned to draw correctly, but the work is full of charm and distinction. The archaic representation of a fisherman on the left illustrates the pioneer work out of which sprang the golden age of Ægean art. This figure, in spite of its crudeness—with full view shoulders, and legs in profile, absence of hands, and monstrous eye—is yet full of vitality and movement, and seems to herald the coming of the period which has high-spiritedness and freedom among its chief characteristics.

Two important Aids
in the preparation of
Peptonised Milk, etc.

Liquor Pancreaticus (Benger)

An active solution of the digestive principles of the Pancreas ; a really efficient agent for the partial digestion of milk, gruel, and farinaceous or partly farinaceous foods. *Benger's Liquor Pancreaticus is odourless and tasteless.*

In 4, 8 and 16 oz. bottles.

Peptonising Powders (Benger)

These powders are double strength and produce the same effect as the Liquid preparation, but possess advantages from the point of view of portability, etc. *Benger's Peptonising Powders—instantly soluble.*

In 1/- and 1/8 boxes (glass tubes).

"The great value of such foods has been elucidated by Sir William Roberts, whilst Mr. Benger has been able to prepare solutions capable of rapidly producing this result."
—Professor Stirling.

Medical men may obtain full particulars of any of Benger's preparations, post free on request.

A Concentrated Nutrient

*containing Bone Marrow (12½%),
Yeast Extract and their associated
accessory factors (A. & B.), together
with Hæmoglobin & Malt Extract.*

'Bynotone'

TRADE MARK

is a concentrated nutrient of wide applicability in the treatment of malnutrition in infants, adolescents and adults. It also provides a source of supply of accessory food factors which are necessary for normal metabolism particularly in infancy but also in adult life.

'Bynotone' is in the form of a granular powder and thus presents its various elements in a highly concentrated form. The preparation is not unduly hygroscopic and keeps perfectly if the container is well closed.

Full particulars and a clinical trial sample sent upon request.

The Management of an Infant's Diet

MELLIN'S FOOD contains 58.88 per cent. of Maltose.

MELLIN'S FOOD contains 20.69 per cent. of Dextrins.

A PROPORTION OF

MALTOSE & DEXTRINS

Best suited to the Carbohydrate needs of the average baby.

MELLIN'S FOOD contains 10.35 per cent. of Cereal Protein.

MELLIN'S FOOD contains 4.30 per cent. of Salts which consist mainly of Potassium Salts, Phosphatic Salts, and a small amount of Iron.

These facts should be considered in selecting a modifier of milk for infant feeding, for these facts indicate some of the reasons for the success of MELLIN'S FOOD which probably is unparalleled since the beginning of the study of the scientific feeding of infants.

GOLD MEDAL, INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

MIST. HEPATICA CONC. (HEWLETT'S).

COMPOSITION.—Ext. Cascarae, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does NOT come under the Dangerous Drugs Act.

THIS excellent compound, first introduced as a general aperient and cholagogue, has now become a popular remedy, and attention has very recently been called to the value of the mixture, by various authorities, in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis, the mixture can be prescribed with wonderful effect, positively curing cases that have resisted other remedies.

The dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 10-oz., 22-oz., 40-oz., and 90-oz. Bottles. Price in England, 12/6 per lb.

Please write: "Mist. Hepatica Conc. (HEWLETT'S)" to ensure obtaining this Preparation.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

BOWEN'S old INVALID PORT

IN recommending a Port of guaranteed purity, doctors will guard their less discriminating patients against the deleterious effects of cheap adulterated wines.

The purity of Bowen's Old Invalid Port is fully attested by independent analysis. It is the pure juice of the Douro grape, mellowed only by the slow hand of time. As a strengthener during convalescence, for lassitude and nervous disorders, its tonic properties are unrivalled.

4/6

Per Bottle.

Sample, Quarter Bottle will be sent free on receipt of professional card.

The Laboratory,
Bow & Bromley Institute,
London, E.
March.

"I have carefully analysed and dietetically examined the Invalid Port submitted to me, and found the Wine to be an exceptionally pure product, thoroughly aged, and possessing a most delicate flavour and bouquet.

From the result of my experiment, I can testify to the genuine character and dietetic qualities, and unhesitatingly certify it to be a high-class Wine of great purity."

(Signed) JOHN GOODFELLOW, P.L.D., F.R.M.S.

INFANT FOODS

—The Question of Starch.

Doctors, Nurses, Welfare Workers, &c., need have no fear that the presence of Starch detracts from the value of ROBINSON'S "Patent" BARLEY as a diluent of milk.

Analysis shows that the actual quantity of starch in Barley Water made from ROBINSON'S "Patent" BARLEY is only 0.552 per cent., when it is made according to directions. That is practically a negligible quantity.

ROBINSON'S "Patent" BARLEY

When human milk is deficient, cow's milk (fresh, dried or condensed) diluted with Barley Water made from ROBINSON'S "Patent" BARLEY, is the nearest substitute for mother's milk.

100 Years' Reputation.

are prepared to appoint a NON-RESIDENT MEDICAL OFFICER on the Staff of this Institution.

Candidates must be duly registered according to the provisions of the Medical Acts, and not over the age of thirty-five.

The gentleman appointed will be required to commence his duties about September, and must give his whole time to the service of the Institution in such a way as may be directed.

At the end of the first year of service the Committee may give permission for private practice.

For salary and other particulars, apply to the Secretary, to whom testimonials must be sent on or before July 10th.

Card with address should be enclosed. H. MERRETT STOCK, Secretary.

Albion Chambers, Bristol.

Applications are invited from qualified

Medical Men for the post of MEDICAL SUPERINTENDENT of the EAST LANCASHIRE TUBERCULOSIS COLONY, Barrowmore Hall, Great Barrow, near Chester. Candidates are required to have experience in the institutional treatment of Tuberculosis, and preference will be given to one with experience in the organisation of employment for Tuberculous patients. Salary £800 per annum, with house, light, and fuel.

The Colony is provided by the East Lancashire Joint County Committee of the Order of St. John and the British Red Cross Society, under whose direction the Medical Superintendent will work.

Applications, enclosing copies of three recent testimonials, stating age, experience, qualifications, &c., should be addressed to the Secretary, East Lancashire Joint County Committee, 3, St. James's-square, Manchester, not later than July 18th.

Royal Berkshire Hospital.—The

Board of Management invite applications for the appointment of an HONORARY PHYSICIAN. Candidates must be Fellows or Members of the Royal College of Physicians of London or Medical Graduates of one of the Universities of Great Britain or Ireland, and must be registered. Preference may be given to candidates who fulfil the conditions laid down in the rules governing the Membership of the Royal College of Physicians of London on the 14th November, 1911.

The elected candidate will be appointed for the period ending on the third Tuesday in January, 1924, and will be eligible for re-election.

Canvassing by, or on behalf of, a candidate will disqualify him.

Candidates are required to provide sixty-five copies of their applications and testimonials, which must be addressed to the Secretary and reach him not later than July 7th, 1923. No testimonials will be required from candidates who are members of the existing medical staff.

The election will be held on July 17th, 1923.

By order. HERMAN BURNLEY, Secretary.

Reading, 26th June, 1923.

Oldham Royal Infirmary.—Applica-

tions are invited for the following posts vacant on July 1st, 1923:—

1. HOUSE SURGEON to Casualty, Out-patient, and Special Departments.

2. HOUSE SURGEON to Women's and Children's Wards.

3. HOUSE SURGEON to Men's Wards.

Salary £200 in each case, with board, residence, and laundry. Appointments tenable for six months, with eligibility to apply for one or other posts not previously held.

Applications marked "House Surgeon," stating age, experience, and nationality, with copies of three recent testimonials, to be submitted forthwith to the undersigned.

CHARLES D. DRAKE, General Superintendent.

Royal Salop Infirmary, Shrewsbury.

Containing 130 Beds.—HOUSE PHYSICIAN required at once. Candidates must be duly registered under the Medical Acts. British and unmarried. (Ladies ineligible.)

Salary at the rate of £160 per annum, with board, residence, and laundry.

The duties consist of being responsible to the Medical Staff for the Medical cases, assisting the Pathologist, and acting as Anæsthetist.

Preference given to those with previous experience as Anæsthetist.

The House Physician is the Junior Resident Officer.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials (not less than three), to be sent to the undersigned forthwith.

26th June, 1923.

ALFRED SUGDEN, Secretary.

County Borough of Southampton.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation invite applications for the position of Assistant Medical Officer of Health at a salary of £500 per annum, to carry out duties in connection with the Port, including the operation of the Aliens Order, 1920, regulations under the Public Health (Regulations as to Food) Act, 1907, and the regulations with respect to Cholera, Yellow Fever, and Plague, &c.

Preference will be given to candidates with some experience in Port Sanitary work, Infectious Fevers, and the treatment of Venereal Disease.

The appointment will be subject to the approval of the Ministry of Health.

The gentleman appointed will be required to devote the whole of his time to the duties of the office and to act under the direction of the Medical Officer of Health.

Forms of application may be obtained from the Medical Officer of Health, Municipal Offices, Southampton.

Applications on the prescribed form, endorsed "Assistant Medical Officer of Health," and stating age, qualifications, experience, &c., together with copies of not more than three recent testimonials, must be delivered at the Town Clerk's Office, Municipal Offices, Southampton, before noon on the 7th July proximo.

22nd June, 1923.

R. R. LINTHORNE, Town Clerk.

Salford Union Infirmary,

Hope, Pendleton, near Manchester.

THIRD ASSISTANT RESIDENT MEDICAL OFFICER (MALE).

FOURTH ASSISTANT RESIDENT MEDICAL OFFICER (FEMALE).

The Guardians of the Salford Union are prepared to receive applications for the above appointments.

Candidates to be eligible must be unmarried, registered under the Medical Acts, and possess a Medical and Surgical qualification. Preference will be given to candidates with experience of Poor-law or General Infirmarys and possessing experience of X-Ray and Electrical work.

The salary for each appointment is £200 per annum, with furnished apartments, attendance, and rations at the Infirmary.

The appointments, which will be subject to the approval of the Ministry of Health, will be made, in the first instance, for six months. The Guardians expect the persons appointed to remain for this period and to devote their whole time to the duties, and also to act as may be directed by the Medical Superintendent as respects the Union Infirmary and other Institutions of the Union.

The Infirmary contains about 910 beds, is well equipped, and provides excellent all-round clinical experience of all classes of Surgical, Medical, and Children's Diseases, a large proportion of which are of an acute nature.

Applications, stating age, qualifications, and experience, and accompanied by copies of not more than three recent testimonials (which will not be returned), should reach me as early as possible, but not later than 9 A.M. on Tuesday, the 10th July, 1923, endorsed "Third (or Fourth) Assistant Medical Officer."

Canvassing the Guardians will disqualify.

By order.

E. H. INCHLEY, Clerk to the Guardians.
Poor-law Offices, Eccles New-road, Salford.
20th June, 1923.

County of Essex.

HALSTEAD AND BELCHAMP UNITED SANITARY DISTRICTS.

*The only aid to hearing
worn by the Right
Hon. W.M. Hughes,
Ex-Prime Minister
of Australia*

The **FIRST AID**
and still the **BEST AID**
to
HEARING—

YEARS and years before any other electrical aid to hearing was even *thought* of the AcoustiCON, the pioneer and original instrument, was helping DEAF people to hear better. The AcoustiCON was the very FIRST Aid to hearing in its field. It is still, as many, many thousands of users will testify, the very BEST Aid. Every *genuine* AcoustiCON is stamped with the name AcoustiCON and its registered number. Beware of imitations. The only PERFECT Aid is the AcoustiCON, which is recommended by more leading Ear Specialists than ALL OTHER INSTRUMENTS COMBINED. The

which is also used exclusively in the Royal Free and London Hospitals by many deaf doctors themselves, and is, furthermore, supplied to leading Institutions, Churches and Public Buildings, will collect and transmit to deaf ears sounds which are right outside the range of other aids. There are no tinny or buzzing sounds with the AcoustiCON; it is beautifully made, light, and can be worn with practical invisibility.

May we demonstrate The AcoustiCON to you?

18, HANOVER STREET, REGENT STREET, LONDON, W.1
14, St. Ann's Sq., MANCHESTER. 75, Buchanan Street, GLASGOW.
66a, Bold Street, LIVERPOOL. 19, Shandwick Place, EDINBURGH.
